The cost includes funding for Aegis Weapon System upgrades that will be fielded with the missile.

The SM-3 Block IIA program faces significant technology development challenges. Six of the program's eight critical technologies are immature and require additional development and testing before they can be demonstrated in a system prototype. In addition, four key components failed to complete their subsystem preliminary design reviews in fiscal year 2011, prompting a rebalancing of requirements, the substitution of some components, and an overhaul of the development schedule. Some of the program's critical technologies will need to be modified to address issues found during these reviews. The revised program schedule adjusted system-level design reviews and added more time for development. This will increase program costs, but it also has the potential to reduce acquisition risk and future cost growth and schedule delays.

2195 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

BMDS: SM-3 Block IIA Program

Technology Maturity

The SM-3 Block IIA program faces significant technology development challenges. The majority of the SM-3 Block IIA components are new technology compared to the SM-3 Block IB. The program must develop a new propulsion system with a much greater thrust, a new divert and attitude control system, a more capable seeker, and use new solid fuel, all of which pose significant technological challenges. The development of similar components has been a challenge for previous SM-3 interceptors.

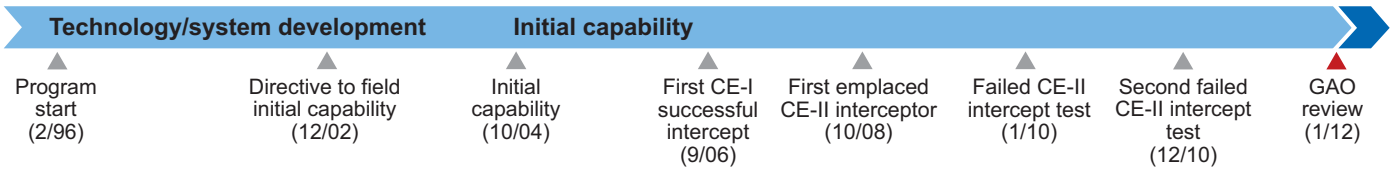
The SM-3 Block IIA program has identified eight critical technologies—six of which are immature and require additional development and testing before they can be demonstrated in a system prototype. The program held subsystem preliminary design reviews during fiscal year 2011, which demonstrated that some critical technologies required redesign or other adjustments. The program has plans in place to rebalance SM-3 Block IIA requirements or replace certain technology components. For example, the program has moved away from a component that has caused problems for the SM-3 Block IB. The program completed new reviews for the four technologies that failed to complete the initial reviews by early fiscal year 2012. In addition, two critical technologies—the second- and third-stage rocket motors—have experienced problems during testing. The program was investigating the causes of those problems and the potential effects at the end of fiscal year 2011. According to the program, all critical technologies will be nearing maturity by its planned September 2013 critical design review.

Other Program Issues

The SM-3 Block IIA program has extended its development schedule by more than a year, which likely will increase program costs, but lower the risk of further cost growth and schedule delays in the future. The program adjusted its system-level preliminary and critical design reviews after several key components failed their preliminary design reviews. The adjustment may reduce acquisition risk and the potential for future cost growth by providing the program more time to reconcile gaps between requirements and resources; demonstrate technical knowledge; and ensure that requirements are defined, feasible, and achievable before committing to product development. The new schedule also lowers risk in other ways, such as building in more recovery time between program reviews and flight tests. Under the revised schedule, flight tests will be delayed from 2015 to late 2016. The SM-3 Block IIA is still planned to be deployed with Aegis Weapons System 5.1 as part of the European Phased Adaptive Approach Phase III in the 2018 time frame.

Program Office Comments

In commenting on a draft of this assessment, Aegis BMD program management officials noted the SM-3 Block IIA program held 60 component-level preliminary design reviews in fiscal year 2011, of which 4 did not receive a pass during the first evaluation. This result drove a schedule adjustment of 1 year. The officials further noted the program used this additional time to implement a more robust engineering process. Actions the program took resulted in the completion of the four component-level reviews and support the completion of the system-level preliminary design review in March 2012. The rebalancing of the component-level requirements that occurred has not affected system-level requirements. Finally, the officials note that the program is on schedule to achieve its European Phased Adaptive Approach objectives. MDA also provided technical comments, which were incorporated as appropriate.



2196 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

BMDS: Ground-Based Midcourse Defense (GMD)

MDA's GMD is being fielded to defend against limited long-range ballistic missile attacks during their midcourse phase. GMD consists of an interceptor with a 3-stage booster and kill vehicle and a fire control system, which formulates battle plans and directs components that are integrated with BMDS radars. We assessed the maturity of all GMD critical technologies and the design of the Capability Enhancement II (CE-II) configuration of the Exoatmospheric Kill Vehicle (EKV), which began emplacements in fiscal year 2009.

Costs are from program inception through fiscal year 2016.

MDA has used a highly concurrent development, production, and fielding strategy for CE-II interceptors, which carried significant risks, some of which were realized after its latest flight test failure. Twelve CE-II EKVs have been manufactured and delivered, but both attempts to verify its capability in flight have failed—the first because of a quality issue and the second because of a failure in the guidance system. The guidance system failure has resulted in design changes, and the risk of further changes on the program will remain until flight testing is complete. The program plans to verify the guidance system fixes through a nonintercept flight test in fiscal year 2012 and has halted the final integration of the remaining CE-II EKVs until it does so. The cost of the CE-II test failures, including costs of failure review, testing, redesigns, and retrofits, could exceed $1.2 billion.

2197 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

BMDS: GMD Program

Technology Maturity

All nine technologies in the GMD operational configuration are mature, but two technologies in the enhanced CE-II interceptor—an upgraded infrared seeker and onboard discrimination—are only nearing maturity. Although the program has manufactured and delivered over 12 CE-II EKVs, its capability has yet to be demonstrated because it failed in its two intercept flight test attempts.

Design and Production Maturity

The GMD program has released all of its expected design drawings to manufacturing and has manufactured and delivered 12 interceptors, but the program remains at risk for design changes until it completes its flight test program, currently scheduled for 2021. For example, the December 2010 CE-II EKV intercept test failure resulted in design changes to resolve problems with the guidance system. These design changes are currently undergoing testing. Additionally, the interceptor design could still change because two of its technologies are not fully mature and have not had their capability verified through flight testing. We did not assess the maturity of production processes for the GMD interceptors. According to the program, the low number of planned quantities does not provide sufficient data to demonstrate its manufacturing processes are in statistical control.

Other Program Issues

MDA has used a highly concurrent development, production, and fielding strategy for CE-II interceptors, which carried significant risks, some of which were realized after its latest flight test failure. That failure has disrupted production, increased costs, and delayed fielding. GMD conducted an intercept flight test to assess the capability of the CE-II EKV in January 2010; however, it did not intercept the target because of a quality-control issue in the EKV. GMD reconducted this test in December 2010 and, although the booster and EKV launched successfully, the EKV failed to achieve an intercept because of a failure in the guidance system. After the test failure, the Director, MDA, halted the planned delivery of CE-II EKVs. In addition, the program deferred other planned fiscal year 2011 work in order to fund the activities necessary to conduct the failure investigation, as well as the resulting redesign efforts. The program plans to verify the fixes it is developing through a nonintercept flight test in fiscal year 2012. The flight test failures have cost MDA hundreds of millions of dollars thus far, and the eventual cost to demonstrate the CE-II through flight testing is likely to be around $1 billion. In addition to the costs of the actual flight tests, the Defense Contract Management Agency reported that mitigating the hardware problems that contributed to the failures will be very expensive and time consuming.

Consequently, the program will have to undertake another major retrofit program for the CE-II EKVs that have already been manufactured. According to GMD program officials, the total cost for this retrofit effort has not been determined, but they expect the effort to cost about $18 million per fielded interceptor resulting in an additional cost of $180 million.

Program Office Comments

In commenting on a draft of this assessment, MDA provided technical comments, which were incorporated as appropriate.

2198 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

BMDS: Terminal High Altitude Area Defense (THAAD)

MDA's THAAD is being developed as a rapidly-deployable, ground-based missile defense system with the capability to defend against short- and medium-range ballistic missiles during their late midcourse and terminal phases. A THAAD battery includes interceptors, launchers, an X-band radar, a fire control and communications system, and other support equipment. MDA is scheduled to deliver the first two of nine planned THAAD batteries to the Army in fiscal year 2012 for initial operational use.

Costs are from program inception through fiscal year 2016.

THAAD's major components are mature and its design is currently stable. The number of design drawings has increased by about 30 percent since production began in 2006, due in part to design changes on a critical safety system. Production issues, driven mostly by design changes, have delayed interceptor deliveries by 18 months and have cost the program nearly $40 million. In fiscal year 2011, the program mitigated some of these issues and was able to meet or exceed its production goals for the first several months of fiscal year 2012. The program still must demonstrate that it can steadily produce at this rate over time. THAAD also conducted its first operational flight test in October 2011—a significant event for the program.

2199 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

BMDS: THAAD Program

Technology and Design Maturity

The THAAD program's major components—the fire control and communications system, interceptor, launcher, and radar—are mature, and the prime contractor has released all of the expected design drawings. However, the number of design drawings has increased by approximately 30 percent since production started in December 2006, due in part to design changes for a safety system called an optical block, which prevents inadvertent launches, and associated changes to the flight sequencing assembly, which houses the optical block. According to program officials, the program considered further design changes, which were estimated to cost approximately $150 million, to the optical block in fiscal year 2011 to make it more producible. However, program management decided not to make those changes because of improved manufacturing performance and program funding constraints. In addition, the current design was demonstrated in an October 2011 flight test and in other testing needed to support an upcoming materiel release decision. Therefore, the program determined that the benefits of continuing the redesign no longer justified the cost.

Production Maturity

MDA awarded a contract for its first two initial operational batteries in December 2006 before developmental testing of all of the system's critical components had been completed. Production issues have delayed interceptor deliveries for the first two batteries by 18 months and have cost the program nearly $40 million. We have previously reported that design changes and producibility issues prevented the interceptor subcontractor from demonstrating the program's planned production rate. The program devised a new testing process to increase production and, according to program officials, the production-rate goal was met in early fiscal year 2012. However, they noted that production rates might be artificially high because the program was able to amass other subcomponents while it was working through interceptor production issues. Consequently, the program still must demonstrate that it can steadily produce at this rate.

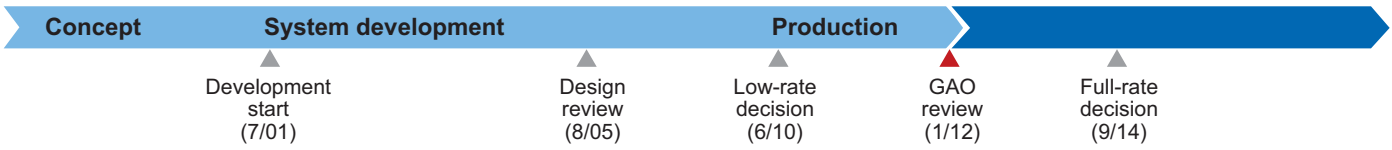
Other Program Issues

THAAD conducted its first operational flight test in October 2011—a significant event for the program. Army and DOD test and evaluation organizations were both involved to ensure that the test's execution and results were representative of the operational environment for the fielded system. During the test, the THAAD system engaged and simultaneously intercepted two short-range ballistic missile targets. Army and MDA test organizations will use this test to conduct an operational assessment of the THAAD system. DOD's independent test organization will also use the results to evaluate THAAD's operational effectiveness.

The THAAD program is expecting the system to be approved for conditional materiel release to the Army in the second quarter of fiscal year 2012. For materiel release to occur, the Army must certify that the batteries are safe, suitable, and logistically supported. Conditional materiel release is an interim step in the Army's process and was originally expected to occur in September 2010, but was delayed first by interceptor safety issues, and more recently by the decision to consider data from THAAD's October 2011 operational flight test. A date for the Army's full materiel release decision has not been established. According to program officials, MDA cannot set a target date until it receives the Army's definitive list of conditions that need to be met and funding to address them.

Program Office Comments

In commenting on a draft of this assessment, MDA provided technical comments, which were incorporated as appropriate.



2200 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

C-130 Avionics Modernization Program (AMP)

The Air Force's C-130 AMP will standardize and upgrade the cockpit and avionics for the three combat configurations of the C-130 fleet. The upgrades are intended to ensure that the C-130 can satisfy the navigation and safety requirements it needs to operate globally. The program will also replace many systems that are no longer supportable due to diminishing manufacturing resources. These efforts are expected to increase the reliability, maintainability, and sustainability of the upgraded aircraft.

Program Essentials

Prime contractor: Boeing
Program office: Wright-Patterson AFB, OH
Funding needed to complete:
R&D: $42.2 million
Procurement: $3,890.4 million
Total funding: $3,932.6 million
Procurement quantity: 208

Program Performance (fiscal year 2012 dollars in millions)

	As of 07/2001	Latest 12/2010	Percent change
Research and development cost	$775.4	$1,948.3	151.3
Procurement cost	$3,356.8	$4,256.0	26.8
Total program cost	$4,132.3	$6,204.3	50.1
Program unit cost	$7.962	$28.074	252.6
Total quantities	519	221	-57.4
Acquisition cycle time (months)	NA	NA	NA

The C-130 AMP entered production in 2010; however, it experienced a greater number of design changes than anticipated in fiscal year 2011 as new software was added to address deficiencies found in testing. The program's critical technologies are mature and a 2008 production readiness review concluded that production processes were mature and ready to start initial production. The program plans to award a second low-rate production contract and that contractor will compete with Boeing for the full-rate production contract. Maturity of production processes for the second source will be assessed prior to the contract award. The full-rate production decision has slipped from February 2013 to September 2014 to provide the second contractor sufficient hands-on experience with AMP kit installation to compete. Officials reported that during the delay, Boeing will also address software issues.

2201 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

C-130 AMP Program

Technology and Design Maturity

The C-130 AMP's critical technologies are mature and its design appears stable; however, the program experienced a somewhat greater number of design changes than anticipated in fiscal year 2011. According to the program office, all of the expected engineering drawings for the C-130 AMP combat delivery configuration were releasable to manufacturing, but a software build was added to the program to address problems found in developmental testing. Specifically, testers found that the core avionics were not well adapted to the C-130's tactical missions and crew workload needed to be reduced during airdrop and low-level operations, as well as those flown in certain formations. The software to address these deficiencies will not be completed and evaluated in time to be included in initial operational test and evaluation. Program officials said the software will be tested beginning in August 2012, a month after operational testing is scheduled to be completed. Officials expect software testing to be completed in advance of the program's full-rate production decision.

Production Maturity

The C-130 AMP received approval to enter low-rate production in June 2010—2 years after a production readiness review concluded that the processes used by Boeing and an Air Force air logistics center were mature and ready to start initial production. Three aircraft have received the AMP modification and the program is meeting or exceeding the quality metrics on which it provided data. However, the program did not assess the manufacturing readiness of key suppliers prior to production. Program officials plan to do so in 2012 and will develop manufacturing maturity plans as needed in order to demonstrate the suppliers' readiness to begin full-rate production.

According to program officials, Boeing will provide all 26 low-rate initial production AMP kits and up to nine installations for the first five production lots. An Air Force logistics center will install kits for the first and second lots of production. Installation of kits for lots 3 through 5 will be completed by Boeing and an Air Force logistics center, as well as a second industry source, to facilitate competition with Boeing for the full-rate production contract. Program officials expect to award a contract to the second contractor in January 2012. Program officials reported that the maturity of production processes of contractors being considered for lots 3 through 5 will be assessed prior to the contract award.

Other Program Issues

The program's full-rate production decision has been delayed 19 months, from February 2013 to September 2014. Program officials stated the delay was necessary to provide a second contractor sufficient hands-on experience with AMP kit installation prior to the contract award for full-rate production. They reported that the program added a fifth low-rate production lot to provide time for the second contractor to accumulate this experience and avoid a production break. The second contractor will compete with Boeing for the full-rate production contract to build and install the AMP kits. An Air Force air logistics center will continue to install AMP kits during full-rate production as well. Program officials stated the delay in full-rate production will also give the program adequate time to complete and test the additional software build.

Program Office Comments

In commenting on a draft of this assessment, the Air Force stated that a source-familiarization phase is being implemented during low-rate initial production to provide a second contractor with sufficient hands-on AMP kit installation experience. The second contractor will then compete with Boeing in a limited competition for full-rate production. Officials also noted that in December 2010, the full-rate production decision was moved from February 2013 to September 2014 to provide the second contractor sufficient hands-on experience prior to proposal submittal to ensure a robust competition. The Air Force also provided technical comments, which were incorporated as appropriate.

GAO Response

After we completed our assessment, DOD proposed cancelling the C-130 AMP program in the President's Budget for Fiscal Year 2013.

2202 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CH-53K - Heavy Lift Replacement

The Marine Corps' CH-53K heavy-lift helicopter is intended to transport armored vehicles, equipment, and personnel to support operations deep inland from a sea-based center of operations. The CH-53K is expected to replace the legacy CH-53E helicopter and provide increased range and payload, survivability and force protection, reliability and maintainability, and coordination with other assets, while reducing total ownership cost.

Acquisition cycle time (months)	119	157	31.9

The CH-53K program completed its critical design review in July 2010 with a stable design, but without fully maturing its critical technologies or demonstrating that its design can perform as expected. As a result, the risk of design changes remains. Flight testing is expected to begin in 2014 and the program expects its critical technologies to be demonstrated in a realistic environment by its August 2015 production decision. According to program officials, the program has begun building test aircraft, which should help demonstrate its manufacturing processes before production begins. The CH-53K development contract increased by $724 million to better reflect cost estimates the program has reported since 2009, and several key events were delayed. According to program officials, these changes do not affect the dates of the production decision or initial operational capability.

2203 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CH-53K Program

Technology Maturity

The CH-53K program began system development in 2005 with immature critical technologies. After 4 years in development, the program's two current critical technologies—the main rotor blade and the main gearbox—were determined to be nearing maturity in February 2010 after being demonstrated in a relevant environment. The program expects these technologies to be demonstrated in a realistic environment by its planned August 2015 production decision. Flight testing of the program's four engineering development models is expected to begin in 2014.

Design Maturity

The CH-53K design appears stable, but it has not been demonstrated using a prototype to show that it will perform as expected. This will not occur until at least 2013. According to the program office, all of the CH-53K's expected design drawings are releasable. However, the continuing maturation of the program's critical technologies could result in design changes as testing progresses.

Production Maturity

According to program officials, the CH-53K program has begun building developmental aircraft and a ground test vehicle. These test articles are being assembled in the same facility where production of the CH-53K is planned to take place. Production of the ground test vehicle began in July 2011 and the first of four engineering development models entered the production line in January 2012. Additionally, program officials stated the completion of the ground test vehicle has been delayed because of problems with the quality of the main gear box castings. However, they believe these problems have been corrected.

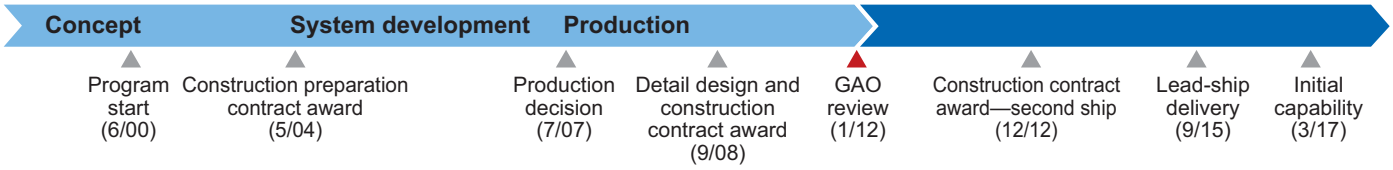
Other Program Issues

The CH-53K development contract has increased in cost and several key events have been delayed. Program officials reported that in July 2011, the contract's estimated cost was increased by $724 million to $3.4 billion. According to Defense Contract Management Agency officials, the estimated contract costs increased because of several factors including the need for additional flight test hours and spare parts, increased material costs, and design complexity. The contract was also changed from cost-plus award fee to cost-plus incentive fee for the remaining period of performance. The incentive fees are tied to specific cost and schedule goals. In August 2011, the contract's schedule was rebaselined and several key production and testing events were delayed. For example, the delivery dates for the program's engineering development models were moved back and its first flight was delayed from 2013 to 2014. According to program officials, these contract changes will not affect the dates for the CH-53K's production decision or delivery of an initial operational capability.

In 2008, the Marine Corps directed the CH-53K program to increase the number of planned aircraft from 156 to 200 to support an increase in strength from 174,000 to 202,000 Marines. In February 2011, the Secretary of Defense testified that the number of Marine Corps troops may decrease by up to 20,000 beginning in fiscal year 2015. According to Marine Corps officials, a force structure review has been conducted to assess the required quantity of aircraft and that review determined that the requirement for 200 aircraft is still valid despite the proposed manpower reduction.

Program Office Comments

In commenting on a draft of this assessment, the Marine Corps provided technical comments, which were incorporated as appropriate.



2204 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CVN 78 Class

The Navy's CVN 78 class of nuclear-powered aircraft carriers are being designed to improve operational efficiency, enable higher sortie rates, and reduce manpower through the use of advanced propulsion, aircraft launch and recovery, and survivability technologies. The Navy awarded a contract for detail design and construction of the lead ship, CVN 78, in September 2008 and expects it to be delivered by September 2015. The Navy plans to award the construction contract for CVN 79 in December 2012 and CVN 80 by the end of 2017.

When the CVN 78 construction contract was awarded in September 2008, the program had several immature technologies and an incomplete three-dimensional product model. The ship's model is now complete, but 7 of the program's 13 critical technologies still have not been tested in a realistic environment. The electromagnetic aircraft launch system (EMALS) and dual-band radar continue to pose cost and schedule risks and neither system will be fully integrated and tested until after they are on-board. CVN 78's procurement cost has grown by about 10 percent over the past 3 years. Cost growth has been driven by construction cost increases, which the program largely attributes to the immaturity of the ship's technologies and design when the construction contract was awarded. The cost growth may require the program to request additional funding or reduce the ship's capabilities.

2205 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CVN 78 Class Program

Technology Maturity

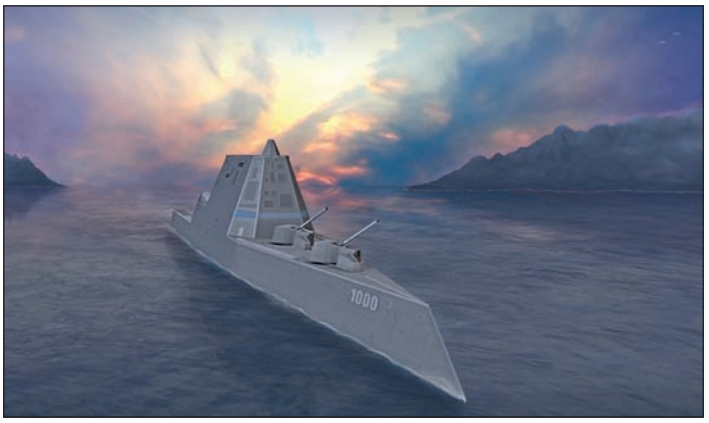
Seven of the CVN 78 program's 13 current critical technologies have not been tested in a realistic, at-sea environment, including two technologies—EMALS and the dual-band radar—which continue to pose risks. According to program officials, EMALS has successfully launched F/A-18E, T-45C, C-2A, and E-2D aircraft during testing; however, the system has not demonstrated the required level of reliability because of the slow correction of problems discovered earlier in testing. In addition, according to officials, EMALS motor generators have only been tested in a group of 4, rather than the group of 12 that will make up the system. A test of the complete system will not take place until it is aboard the ship. The dual-band radar also will not complete testing until after it is aboard the ship, which presents a risk if the system does not work as intended. The radar is required for ship installation starting in March 2013, but the program does not expect to complete testing the multifunction radar component until early 2013 or begin testing the volume-search radar component until May 2013. Some radar subsystems will not be tested until aboard the CVN 78. In addition, less dual-band radar testing has been done than anticipated because the Navy eliminated the volume-search component of the radar from the DDG 1000 Destroyer program, which the CVN 78 had planned to leverage. CVN 78 will now be the first ship to operate with this radar, but as of August 2011, the Navy had not yet planned for carrier-specific testing. Program officials also noted that the Evolved Sea Sparrow Missile will be demonstrated in a relevant environment by March 2012, at which point all critical technologies will have been demonstrated in a relevant environment.

Design Maturity

The CVN 78 program completed its three-dimensional product model in November 2009—over a year after the award of the construction contract. At the time of the September 2008 contract award, only 76 percent of the ship's three-dimensional product model was complete and the shipbuilder had already begun construction of at least 25 percent of the ship's structural units under its previous construction preparation contract. Program officials noted that while there had been concerns about the ability of the ship's jet blast deflectors to work effectively with the carrier variant of the Joint Strike Fighter, these concerns have been addressed and will not require major design changes. Additional design changes are still possible as EMALS and other systems continue testing.

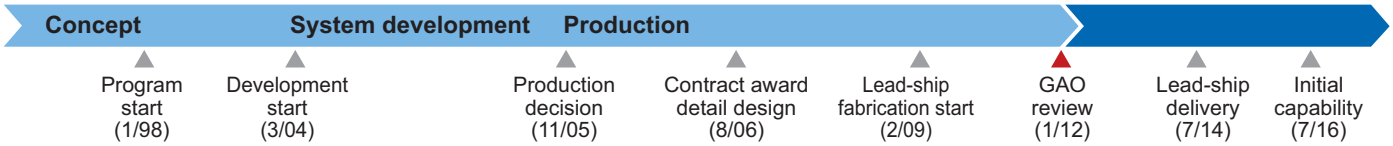
Production Maturity

Procurement costs for CVN 78 have grown by about 10 percent over the past 3 years. A key driver is an increase in construction costs. According to the program, 83 percent of the ship's structural units are complete, constituting almost 27 percent of the expected labor hours. However, the program estimates that the labor hours to complete the ship will be 4 million more than the 40 million hours originally budgeted. The program believes the cost and labor-hour increases are largely due to the immaturity of the ship's technologies and design when the construction contract was awarded. Program officials also cited problems such as late material deliveries, an unexpected need for more structural support to achieve a thinner deck structure, and material deficiencies on developmental components such as valves. According to the program, the growth in construction costs may require requests for additional funding or a reduction of the ship's capabilities.



Program Office Comments

In commenting on a draft of this assessment, the program noted that dual-band radar testing, while impacted by DDG 1000 decisions on volume-search radar, is fully funded and will complete land-based tests and begin shipboard testing prior to delivery.



2206 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

DDG 1000 Destroyer

The Navy's DDG 1000 destroyer is a multimission surface ship designed to provide advanced land-attack capability in support of forces ashore and littoral operations. The ship will feature a low radar profile, an advanced gun system, and a total ship computing environment intended to improve the speed of command and reduce manning. Fabrication has begun on the first two ships and is planned to begin on the third ship in fiscal year 2012.

Total funding: $2,413.6 million
Procurement quantity: 0

Program Performance (fiscal year 2012 dollars in millions)

	As of 01/1998	Latest 08/2011	Percent change
Research and development cost	$2,277.9	$10,378.4	355.6
Procurement cost	$32,522.1	$10,607.2	-67.4
Total program cost	$34,800.0	$20,985.6	-39.7
Program unit cost	$1,087.500	$6,995.214	543.2
Total quantities	32	3	-90.6
Acquisition cycle time (months)	128	222	73.4

The DDG 1000 design is stable and all three ships are in or will soon be in fabrication. However, the program is still conducting development work on several of its critical technologies and most of them will not be fully mature and demonstrated in a realistic environment until after their installation on the ship. One of the technologies—the advanced gun system's long-range land-attack projectile—continued to experience delays due to issues with its rocket motor. The Navy plans to finalize and test the rocket motor design by March 2012. The first two ships are approximately 63 percent and 22 percent complete, respectively. According to program officials, the shipbuilder had to rework some areas on the first ship, which resulted in an 8-week schedule delay, but only minor cost increases. The Navy has noted improvements in fabrication on the second ship.

2207 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

DDG 1000 Program

Technology Maturity

The DDG 1000 program is still conducting development work on several of its critical technologies. Three of DDG 1000's 12 critical technologies are currently mature and the integrated deckhouse will be delivered to the first ship for installation in fiscal year 2012. However, the remaining eight technologies will not be demonstrated in a realistic environment until after ship installation. The Navy has completed a successful full-power test of the integrated power system—one of these eight technologies—and plans a follow-on test in fiscal year 2012. Another critical technology—the total ship computing environment—consisted initially of six software releases. According to program officials, software release 5 has been completed and was used in land-based testing in fiscal year 2011. The program has made changes to release 6, and has prioritized the software needed to support shipyard delivery over the functionality needed for activating the mission systems. This functionality was moved out of the releases and will be developed as part of a spiral. Other key technologies, including the multifunction radar and the advanced gun system, have been delivered to the first ship. However, the gun system's long-range land-attack projectile has encountered delays, primarily due to problems with its rocket motor. The Navy plans to finalize and test the rocket motor design by March 2012. The Navy has performed several guided flight tests using older rocket motor designs, which demonstrated that the projectile can meet its accuracy and range requirements.

Design and Production Maturity

The DDG 1000 design is stable, although the potential for design changes remains until its critical technologies are fully mature. There have been few design changes resulting from lead-ship production, which program officials attribute to a high level of design maturity prior to fabrication. As of January 2012, the Navy estimated that the first ship, which began fabrication in February 2009, was 63 percent complete. The second ship, which began fabrication in March 2010, is 22 percent complete.

Shipbuilders have experienced several challenges in constructing the first and second ships, including issues with the manufacture and installation of certain composite materials. According to program officials, the shipbuilder had to rework some areas, which resulted in an 8-week schedule delay, but only minor cost increases. Program officials noted that the shipbuilder has developed and refined manufacturing and installation processes to reduce the likelihood of rework on the subsequent ships.

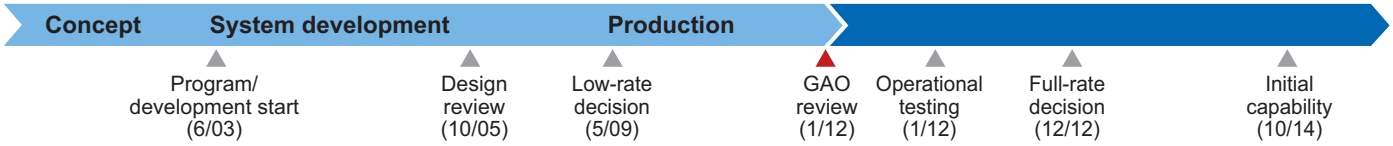
Other Program Issues

Following a Nunn-McCurdy unit-cost breach of the critical threshold in 2010, DOD restructured the DDG 1000 program and removed the volume-search radar from the ship's design. The program will modify the multifunction radar to meet its volume-search requirements.

The Navy recently awarded contracts for fabrication of the third ship, its gun system, and software development and integration. In these negotiations, program officials said the Navy leveraged its knowledge about actual costs from the fabrication of the first two ships and from other programs to reduce costs. According to program officials, the Navy is in negotiations for contracts related to the mission systems and other key segments of the third ship.

Program Office Comments

In commenting on a draft of this assessment, Navy officials confirmed that the program was recertified and restructured in June 2010 following a Nunn-McCurdy unit-cost breach and the curtailing of the program to three ships. Since then, the Navy has awarded ship construction contracts for all three ships, including advanced guns and all required software. All critical technologies have been tested in at least a relevant environment. Officials noted that more than 90 percent of the software has been completed through design, code, unit test, and integration and its schedule is aligned to ship activations. Navy officials also said that program reviews by the Office of the Under Secretary of Defense for Acquisition, Technology and Logistics and DOD's Office of Performance Assessment and Root Cause Analyses concluded that the Navy is managing and retiring program risk. The Navy also provided technical comments, which were incorporated as appropriate.



2208 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

E-2D Advanced Hawkeye (E-2D AHE)

The Navy's E-2D AHE is an all-weather, twin-engine, carrier-based aircraft designed to extend early warning surveillance capabilities. It is the next in a series of upgrades the Navy has made to the E-2C Hawkeye platform since its first flight in 1971. The key objectives of the E-2D AHE are to improve target detection and situational awareness, especially in the littorals; support theater air and missile defense operations; and provide improved operational availability for the radar system.

Source: U.S. Navy.

Program Essentials

Prime contractor: Northrop Grumman
Program office: Patuxent River, MD
Funding needed to complete:
- R&D: $367.8 million
- Procurement: $10,874.7 million
- Total funding: $11,257.5 million
- Procurement quantity: 60

Program Performance (fiscal year 2012 dollars in millions)

	As of 06/2003	Latest 08/2011	Percent change
Research and development cost	$3,841.0	$4,537.9	18.1
Procurement cost	$10,911.1	$13,167.1	20.7
Total program cost	$14,752.0	$17,747.3	20.3
Program unit cost	$196.694	$236.630	20.3
Total quantities	75	75	0.0
Acquisition cycle time (months)	95	136	43.2

The E-2D AHE's critical technologies are mature, its design is stable, and its production processes have been demonstrated. According to E-2D program office and Defense Contract Management Agency (DCMA) officials, the contractor is also performing well on a variety of production metrics. The program continues to make progress completing development test points and addressing issues identified in the 2010 operational assessment, but it delayed initial operational test and evaluation from November 2011 to January 2012. The program office continues to improve the radar's reliability rate, which is currently 71 hours, but DOD test organizations expressed some concern about whether the radar will be able to meet some reliability and performance measures during initial operational test and evaluation.

2209 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

E-2D AHE Program

Technology and Design Maturity

According to the Navy, all five of the E-2D AHE's critical technologies are mature and its design is stable. Program officials told us that an increase in design drawings over the last year was primarily due to changes made to address issues identified during development testing. None of the test discoveries resulted in major changes to the aircraft design, and DCMA officials confirmed that these design changes were relatively minor.

Production Maturity

The E-2D AHE's production processes have been demonstrated. According to the E-2D program office and DCMA officials, the contractor is performing well on a variety of production metrics and the program has not identified any issues that would result in cost or schedule growth on the production contract. The contractor reports monthly to DCMA and the program office on a series of production metrics, such as scrap and rework rates. The program did not identify any critical manufacturing processes associated with the E-2D AHE, nor does the program require the contractor's major assembly site to use statistical process controls to ensure its critical processes are producing high-quality and reliable products because components are assembled using manual processes that do not lend themselves to such measures.

Other Program Issues

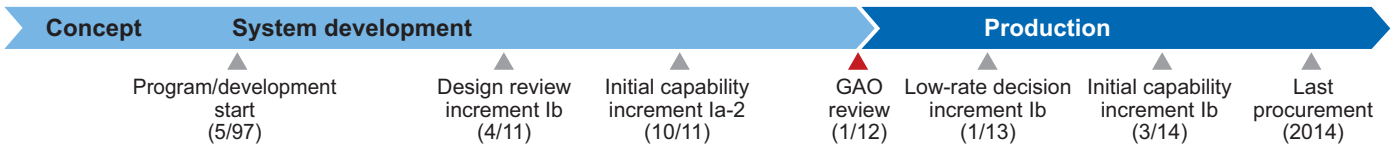
The program continues to make progress completing development test points and addressing issues identified in the 2010 operational assessment, but it delayed initial operational test and evaluation from November 2011 to January 2012. Some development test points related to the Cooperative Engagement Capability (CEC) remain to be completed. The CEC is a system that integrates information from multiple sources to track potential targets and is being developed by a separate Navy program office. The E-2D program could not test this capability as scheduled because of late deliveries from the CEC program. The E-2D program has now received the CEC and plans to test it before the start of initial operational testing.

The program office continues to improve the radar's reliability. The E-2D program reported the current radar reliability rate is 71 hours. The radar must achieve a rate of 81 hours prior to the decision to enter full-rate production, which is scheduled for December 2012. DOD test organizations expressed some concern about whether the radar will be able to meet some reliability and performance measures during initial operational test and evaluation. However, initial results from a test exercise conducted in November partially addressed the performance concerns, according to an official at a DOD test organization.

As part of DOD's better-buying-power initiatives, the E-2D AHE program conducted a should cost analysis prior to the negotiation of its third production contract. According to program officials, it used the results of this analysis to achieve a 4.5 percent cost savings on this contract.

Program Office Comments

In commenting on a draft of this assessment, Navy officials noted that the program has completed all the testing required on the E-2D itself before entering initial operational test and evaluation, although some testing of the CEC system remains. The Navy also provided technical comments, which were incorporated as appropriate.



2210 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Excalibur Precision Guided Extended Range Artillery Projectile

The Army's Excalibur is a family of global positioning system–based, fire-and-forget, 155 mm cannon artillery precision munitions intended to provide improved range and accuracy. The near-vertical angle of fall is expected to reduce collateral damage, making it more effective in urban environments. The Army is using a three-phased approach to deliver capabilities. Increment Ia-1 is fielded, Ia-2 is in production, and Ib, which is expected to increase reliability and lower unit costs, will begin production in 2013. We assessed increment Ib.

Source: U.S. Army.

Program Essentials

Prime contractor: Raytheon
Program office: Picatinny Arsenal, NJ
Funding needed to complete:
R&D: $50.2 million
Procurement: $234.9 million
Total funding: $285.1 million
Procurement quantity: 3,455

Program Performance (fiscal year 2012 dollars in millions)

	As of 02/2003	Latest 08/2011	Percent change
Research and development cost	$765.5	$1,068.3	39.6
Procurement cost	$4,010.8	$712.1	-82.2
Total program cost	$4,776.2	$1,780.5	-62.7
Program unit cost	$.062	$.238	282.4
Total quantities	76,677	7,474	-90.3
Acquisition cycle time (months)	136	173	27.2

Total quantities include 3,455 increment Ib projectiles.

The Excalibur program will have to resolve several increment Ib design issues before its planned January 2013 production decision. In August 2010, the Army began system development for increment Ib with its one critical technology nearing maturity. The increment Ib design review was held in April 2011 and while all the expected design drawings were releasable, parts of the design were found to be incomplete and noncompliant. Additional subsystem design reviews will be required to certify the design is complete. The program is conducting a series of tests in advance of its production decision to ensure performance and safety requirements can be met. Reliability testing will not be complete until after production has begun. The program experienced a Nunn-McCurdy unit-cost breach of the critical threshold in 2010 due to a reduction in quantities, but was certified to continue in 2011.

2211 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Excalibur Program

Technology Maturity

After an 18-month prototype design and demonstration phase, the Army began system development for increment Ib in August 2010 with its one critical technology—the guidance system—nearing maturity. According to the program office, the guidance system is now mature.

Design Maturity

The Excalibur program will have to resolve several increment Ib design issues before its design can be considered stable. The majority of the increment Ib design is complete and all of the program's current design drawings were released by its April 2011 design review. However, the design review panel indicated that three of the eight projectile subassemblies—the base assembly, fuze safe and arm device, and tactical telemetry module—had incomplete designs. Those subassemblies will require additional subsystem-level design reviews and testing before their designs can be considered complete. Further, although the majority of the design appears to comply with current program requirements, the program does not currently meet requirements related to insensitive munitions, the range of the gun, and the fuze setting timeline. Ensuring compliance with these requirements could require design changes, and the program is uncertain of the total number of drawings that will ultimately be required for the projectile.

The program is beginning integrated developmental and operational testing to prepare for the January 2013 production decision for increment Ib. Design verification testing was conducted in May and July 2011 to characterize the performance and structural integrity of the design for the Ib base as well as to gather aerodynamic data on the latest design. The Army also plans to perform sequential environment tests to evaluate the performance, reliability, and lethality of the projectiles under a broad range of conditions. All performance and safety requirements are expected to be met before the production decision. However, reliability testing will not be complete until after production has begun.

Production Maturity

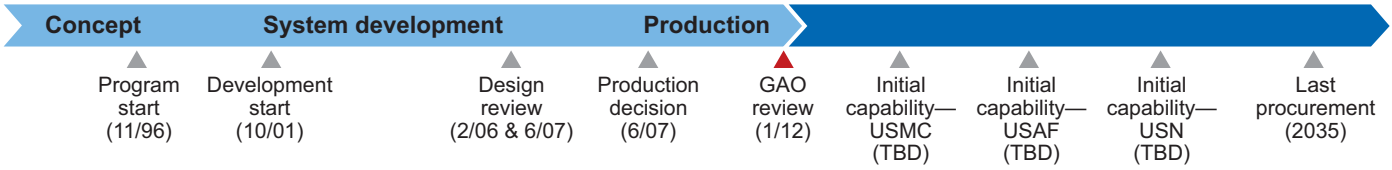
The lack of a complete and stable design has prevented the Excalibur program from demonstrating the level of manufacturing maturity for increment Ib expected for a program that is preparing to enter production. The increment Ib will use similar manufacturing processes as the increment Ia, which the program assesses as mature. However, according to the increment Ib June 2011 capability production document, final manufacturing processes have not yet been demonstrated at two key suppliers because of incomplete or changing designs.

Other Program Issues

In May 2010, the Army reduced program quantities from 30,000 to 6,264 based on a review of precision munition needs. The resulting unit-cost increase led to a Nunn-McCurdy unit-cost breach of the critical threshold. A January 2011 program review concluded that the program is essential to national security and no alternatives are available to provide the same capability at a lower cost. As a result, in January 2011, the restructured Excalibur program was certified to continue. The restructured program plans to save $24 million by increasing the rate of increment Ib production and using fixed-price contracts with economic price adjustments for steel.

Program Office Comments

In commenting on a draft of this assessment, the Army stated that the program does not currently meet requirements related to insensitive munitions due to the lack of a qualified explosive, and the fuse setting due to a new requirement to clear cryptographic keys prior to loading the new key. Ensuring compliance with the insensitive munitions requirement would require an insensitive explosive qualification program and subsequent warhead qualification, which would delay the program and increase costs. The fuze setting timeline is currently within less than one second of the requirement. Changing the requirement to allow the system to overwrite previously entered keys would allow this requirement to be met. The Army further stated that manufacturing processes will be demonstrated and reviewed prior to the production decision. The Army also provided technical comments, which were incorporated as appropriate.



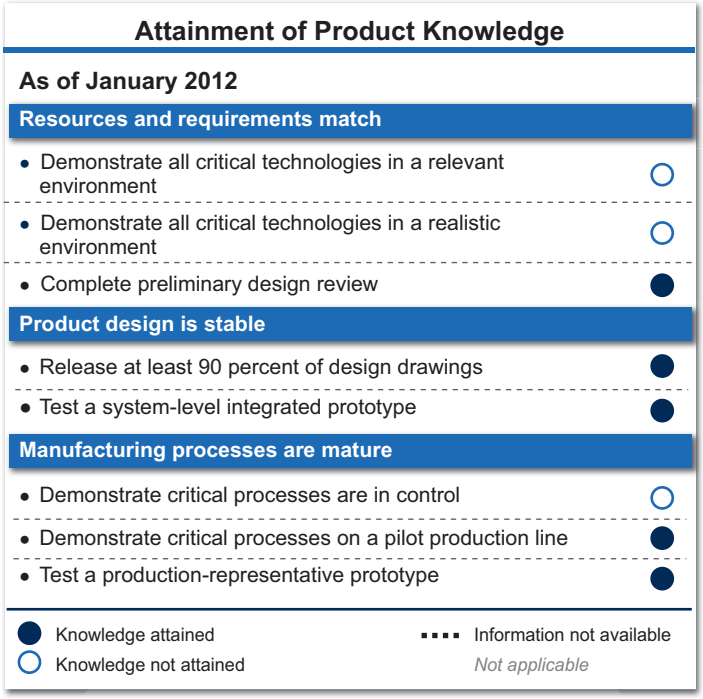
2212 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

F-35 Lightning II (Joint Strike Fighter)

DOD's JSF program is developing a family of stealthy, strike fighter aircraft for the Navy, Air Force, Marine Corps, and U.S. allies, with the goal of maximizing commonality to minimize life-cycle costs. The carrier-suitable variant will complement the Navy F/A-18 E/F. The Air Force variant will primarily replace the air-to-ground attack capabilities of the F-16 and A-10, and will complement the F-22. The short take-off and vertical landing variant will replace the Marine Corps F/A-18 and AV-8B aircraft.

Source: 2010 Lockheed Martin.

Program Essentials



Prime contractor: Lockheed Martin, Pratt and Whitney
Program office: Arlington, VA
Funding needed to complete:
R&D: $10,117.8 million
Procurement: $245,676.5 million
Total funding: $255,970.4 million
Procurement quantity: 2,353

Program Performance (fiscal year 2012 dollars in millions)

	As of 10/2001	Latest 12/2010	Percent change
Research and development cost	$38,976.7	$58,387.6	49.8
Procurement cost	$172,921.4	$267,595.6	54.7
Total program cost	$213,708.2	$326,535.2	52.8
Program unit cost	$74.567	$132.900	78.2
Total quantities	2,866	2,457	-14.3
Acquisition cycle time (months)	116	TBD	NA

Latest column does not fully reflect the restructured JSF program. Costs are expected to grow and the schedule will be extended.

The JSF program has awarded contracts for production aircraft, but it still lacks key knowledge about its technologies and manufacturing processes. Four critical technologies are not mature and present significant development risks as the program integrates and tests them. The program is making progress in flight testing, but much of its developmental and operational testing remains and the risk of future design changes is significant. Manufacturing inefficiencies, parts shortages, and quality issues persist, but there has been some improvement. The program has been restructured to address development challenges, which triggered a Nunn-McCurdy unit-cost breach of the critical threshold. Aircraft quantities have been reduced in the near term to reduce risk and offset increased development funding needs. DOD has not yet approved a new baseline for the program.

2213 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JSF Program

Technology Maturity

The JSF program began system development with none of its eight critical technologies mature; and, according to program officials, four of these technologies—mission systems integration, which includes the helmet-mounted display; the prognostics and health management system; integrated core processor; and integrated support systems—are still not fully mature. Deficiencies in the helmet-mounted display prompted the program to develop a second helmet. The program is also trying to fix the first helmet, which does not currently meet system requirements. Significant development risks remain as the program integrates and tests these technologies.

Design Maturity

The JSF program did not have a stable design at its critical design reviews. The program has now released 96 percent of its total expected design drawings; however, it continues to experience design changes. With most of developmental and operational flight testing still ahead, the risk of future design changes and their potential effects on the program could be significant.

Production Maturity

The JSF program's manufacturing processes have not been fully demonstrated as only 24 percent of the critical processes are in statistical control. The prime contractor has made manufacturing process improvements and some key production metrics are improving. However, manufacturing inefficiencies persist, primarily driven by parts shortages, parts quality issues, and technical changes arising from discoveries during test events, indicating that the aircraft's design and production processes may still lack the maturity needed to efficiently produce aircraft at planned rates. The prime contractor planned to deliver 16 production aircraft in 2011, but only 9 were delivered. Reintroduction of the carrier variant into the production line has resulted in parts shortages and out-of-station work, which can be highly inefficient. The prime contractor is also managing hundreds of suppliers within a global network, which adds to the complexity of producing aircraft efficiently and on-time. In addition, extensive testing remains to be completed and the program could be required to alter production processes, change its supplier base, and retrofit produced and fielded aircraft if problems are discovered.

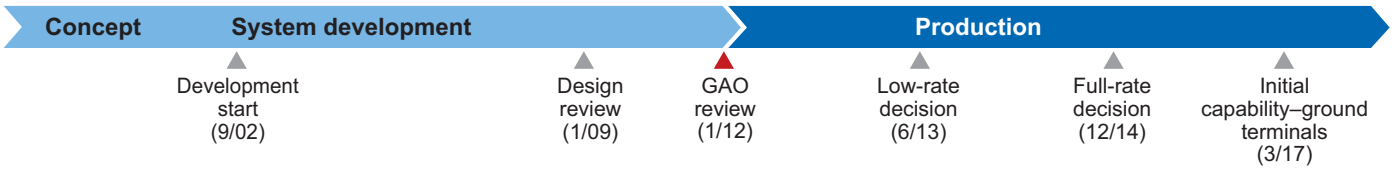
Other Program Issues

DOD has restructured the JSF program by adding more time and money to address development challenges and reducing near-term quantities to reduce risk and offset the additional development costs. The projected cost of the restructured program triggered a Nunn-McCurdy unit-cost breach of the critical threshold in 2010. At the time of our assessment, the program had not yet completed a DOD review at which time the program's updated cost and schedule estimates may be approved. According to program officials, the services are also assessing the effect of the program changes and have not yet determined new initial operational capability dates for any of the variants.

All but one of the initial test assets have been delivered to their respective test locations, and the program made significantly more progress in flight testing compared to the previous year. The short take-off and vertical landing variant successfully completed initial ship trials. However, the program continues to experience challenges in developing and integrating the large and complex software requirements needed to achieve JSF capabilities, which could slow testing.

Program Office Comments

In commenting on a draft of this assessment, DOD noted that the JSF program has 10 years of development and aircraft in production. In reference to the helmet, officials explained that due to the need to demonstrate at the milestone B recertification that all technologies had been demonstrated in at least a relevant environment, the program is adding a second helmet as a risk-reduction effort while continuing to improve the first helmet. The program has a plan to mitigate development risks for the original helmet through developmental testing. DOD also provided technical comments, which were incorporated as appropriate.



2214 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Family of Advanced Beyond Line-of-Sight Terminals (FAB-T)

The Air Force's FAB-T program plans to provide a family of satellite communications terminals for airborne and ground-based users that will replace many program-unique terminals. It is being designed to work with current and future communications capabilities and technologies. FAB-T is expected to provide voice and data military satellite communications for nuclear and conventional forces as well as airborne and ground command posts, including B-2, B-52, RC-135, E-6, and E-4 aircraft.

Source: U.S. Air Force.

Program Essentials

Prime contractor: Boeing
Program office: Hanscom AFB, MA
Funding needed to complete:
R&D: $571.4 million
Procurement: $2,338.6 million
Total funding: $2,910.0 million
Procurement quantity: 216

Program Performance (fiscal year 2012 dollars in millions)

	As of 12/2006	Latest 08/2011	Percent change
Research and development cost	$1,537.1	$2,338.7	52.2
Procurement cost	$1,651.4	$2,349.6	42.3
Total program cost	$3,188.5	$4,688.3	47.0
Program unit cost	$14.762	$19.058	29.1
Total quantities	216	246	13.9
Acquisition cycle time (months)	129	174	34.9

The latest cost data do not reflect the current cost of the program. A new acquisition program baseline has not yet been approved.

The FAB-T program has gained key knowledge about its critical technologies and design, but it faces several cost, schedule, and development challenges. In 2010, the program extended development and has since delayed production by more than 3 years. The program's software development schedule is still unrealistic. There has been an increase in productivity, but development may be completed 4 to 8 months behind the new schedule. In addition, a high-priority presidential and national voice conferencing requirement has not yet been put under contract. The program will likely breach critical Nunn-McCurdy unit-cost thresholds unless it can achieve significant savings from its revised acquisition strategy, which includes competition for FAB-T development and production. There will be continued uncertainty about the program's cost until a new acquisition program baseline is approved.

FAB-T Program

Technology Maturity

According to the FAB-T program, all six of its critical technologies are mature. These technologies have been demonstrated in recent testing—both in-flight and with a satellite simulator.

Design Maturity

The FAB-T's design is currently stable; however, design changes are likely as the program addresses new requirements. The program reported that 98 percent of its total expected design drawings were releasable, but the number of design changes was somewhat greater than anticipated in fiscal year 2011. In addition, the U.S. Strategic Command has requested that a new, high-priority requirement for presidential and national voice conferencing be added to the program. Program officials stated that requirements development and design activities related to this capability began in October 2011, but the engineering changes to the terminal will not be put under contract until spring 2012.

Software development and testing remain major challenges for the program. An April 2011 independent review team found that the software development schedule could not be met without extraordinary productivity growth. In response, program officials told us that they have put in place metrics to manage the effort, revised the test schedule, and increased the government's presence at the contractor's facility. According to program officials, there has been an increase in productivity; however, the program is still behind schedule and development could be completed 4 to 8 months late.

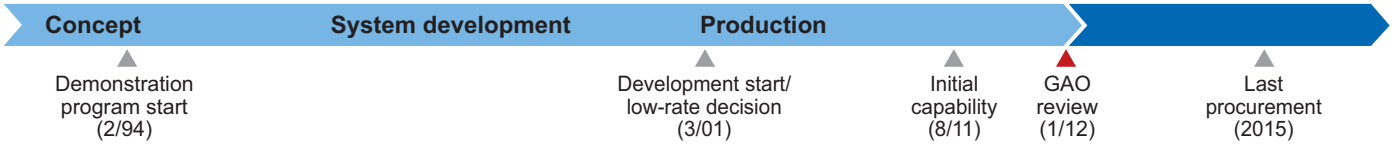
Other Program Issues

The FAB-T program was restructured in 2010 and its acquisition strategy is being revised, but a new acquisition program baseline that reflects these changes and their projected costs has not yet been approved. As part of the restructuring, the program extended its system development phase and delayed its production decision by more than 3 years to June 2013. In October 2010, an independent review team noted that the program was likely in breach of critical Nunn-McCurdy unit-cost thresholds; however, a breach has not yet been reported by the program. The FAB-T program plans to change its acquisition strategy to competitively award contracts for development and production. Program officials said they expect to achieve significant savings in production by using this approach. They also stated that a recent independent cost estimate showed substantial cost growth in the program, but it did not reflect the competitive strategy, which is still under review. A new independent cost estimate, which includes the competitive strategy and new voice conferencing requirement, is expected to be conducted by October 2012.

Due to uncertainty about FAB-T, the Air Force stopped work on contracts related to its integration with the B-2 and B-52—the two bomber platforms for which it is designed. According to officials, both programs are considering alternatives to transmit data through AEHF satellites, which is an important capability for strategic platforms. However, FAB-T might not be able to provide its full range of planned communications capabilities if the bomber programs pursue alternatives since some of its capabilities are based on the interaction of bomber aircraft with intelligence, surveillance, and reconnaissance aircraft and ground terminals.

Program Office Comments

In commenting on a draft of this assessment, the Air Force stated that the FAB-T program is executing the Under Secretary of Defense for Acquisition, Technology and Logistics' January 2012 acquisition decision memorandum, which directed it to establish a competitively awarded fixed-price development and production approach by placing priority on the air and ground command post terminals to provide a presidential and national voice conferencing capability. In addition, the memorandum also directed the program to complete an independent cost estimate and revised acquisition program baseline prior to the award of an alternate source. In parallel with executing the memorandum, the program office is considering converting the current cost-plus award fee contract into a firm fixed-price contract in order to reduce the government's cost risk. The Air Force also provided technical comments, which were incorporated as appropriate.

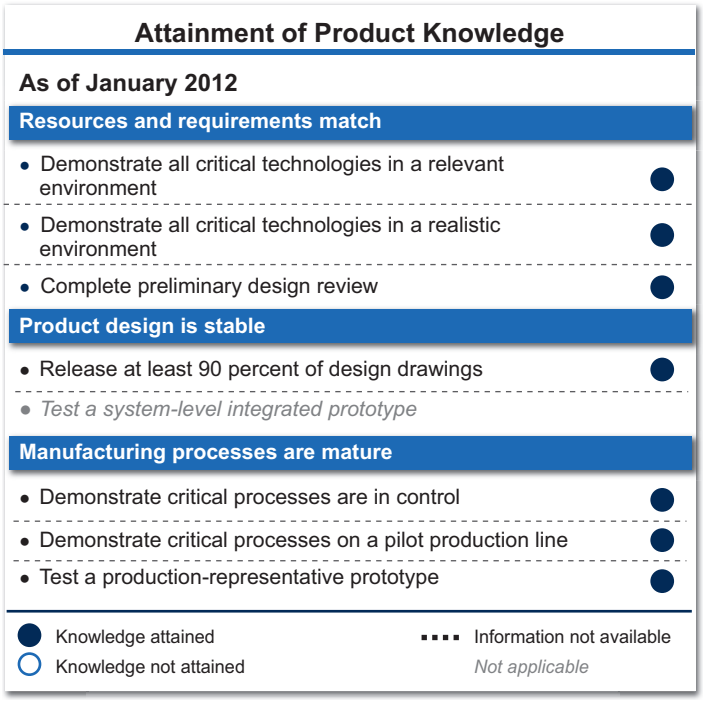


2216 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Global Hawk (RQ-4A/B)

The Air Force's Global Hawk is a high-altitude, long-endurance unmanned aircraft that provides intelligence, surveillance, and reconnaissance capabilities. The Global Hawk will replace the U-2. After a successful technology demonstration, the system entered development and limited production in March 2001. The early RQ-4A, similar to the original demonstrators, was retired in 2011, leaving a fleet of the larger and more capable RQ-4Bs. We assessed the RQ-4B, which is being produced in 3 configurations—block 20, 30, and 40.

Source: Northrop Grumman.



Program Essentials

Prime contractor: Northrop Grumman
Program office: Wright-Patterson AFB, OH
Funding needed to complete:
R&D: $1,657.1 million
Procurement: $3,098.9 million
Total funding: $4,789.4 million
Procurement quantity: 13

Program Performance (fiscal year 2012 dollars in millions)

	As of 03/2001	Latest 10/2011	Percent change
Research and development cost	$1,041.6	$4,769.3	357.9
Procurement cost	$4,318.8	$7,877.4	82.4
Total program cost	$5,392.0	$12,811.6	137.6
Program unit cost	$85.588	$232.938	172.2
Total quantities	63	55	-12.7
Acquisition cycle time (months)	55	125	127.3

The Global Hawk program has utilized a concurrent testing and production strategy, which put it at increased risk of cost growth. The program procured all of its block 20 and more than half of its block 30 aircraft before completing operational testing in 2010 and plans to procure all of its block 40 aircraft before it begins operational testing in 2013. In May 2011, the Director, Operational Test and Evaluation, found that the block 30 system was not operationally effective or suitable and provided several recommendations to improve the aircraft's capability and reliability. The program has addressed most of the test findings. The program also reported a critical Nunn-McCurdy cost breach to Congress in April 2011 and has been restructured. The planned dates for remaining key events have been delayed by an additional 6 months or more and the number of aircraft has been decreased to 55.

2217 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Global Hawk Program

Technology, Design, and Production Maturity

The critical technologies for the RQ-4B are mature, its basic airframe design is stable, and its manufacturing processes are mature and in statistical control. The RQ-4B aircraft is being produced in three configurations. Block 20 aircraft are equipped with an enhanced imagery intelligence payload, block 30 aircraft have both imagery and signals intelligence payloads, and block 40 aircraft will have an advanced radar surveillance capability. All six block 20 aircraft have been produced and production continues on block 30 and block 40 aircraft. However, the program must still successfully test one of its key capabilities for block 40 aircraft—the multiple platform radar—to ensure it performs as expected. Developmental testing of the multiple platform radar is now underway, but the program remains at risk for late design changes if problems are discovered in testing.

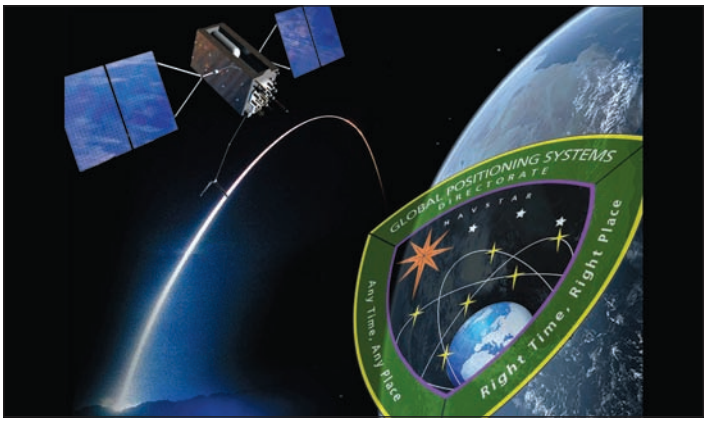
Other Program Issues

The Global Hawk program has utilized a concurrent testing and production strategy, which put it at increased risk of cost growth. The program procured all of its block 20 and more than half of its block 30 aircraft by the time it completed operational testing in December 2010. On the basis of the results of this testing, the Director, Operational Test and Evaluation, reported in May 2011 that the block 30 system was neither operationally effective nor operationally suitable for conducting near-continuous, persistent intelligence, surveillance, and reconnaissance based on the Air Force Concept of Employment, and made several recommendations to improve the system's capabilities, situational awareness, and reliability. According to program officials, they have addressed most of the problems identified in operational testing and have plans in place to correct the remainder. Initial operational capability was declared for block 30 aircraft in August 2011. The program also plans to procure all of its block 40 aircraft before its projected start of operational testing in October 2013, putting it at increased risk of costly retrofits if problems are discovered.

In 2011, the Global Hawk program reported a Nunn-McCurdy unit-cost breach of the critical cost growth threshold and was restructured. The program office attributed the cost growth to changes in the quantities of block 30 and block 40 aircraft, increases in support costs, and the revised architecture of its ground station and communication systems. DOD also pointed to the presence of known, but unfunded, requirements and an unrealistic schedule as root causes for much of the cost growth. The restructured program includes four separate subprograms—block 10/20, block 30, block 40, and ground station and communications. The block 30 and 40 subprograms will hold new production decision reviews in early 2012. The ground station and communications subprogram is scheduled to begin system development in summer 2013. The program also has five performance requirements that were part of its existing baseline that will not be available in the required timeline. As a result of actions taken in DOD's fiscal year 2012 budget and the Nunn-McCurdy process, the planned quantities for the program have been decreased from 77 aircraft to 55 aircraft and aircraft procurement is scheduled to be completed in 2015.

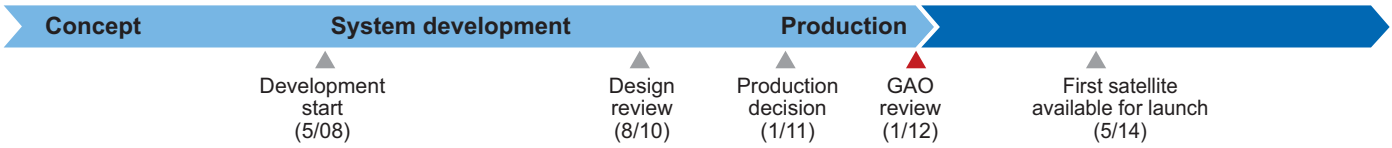
Program Office Comments

In commenting on a draft of this assessment, the Air Force stated that in 2011 the program deployed its block 30 systems and they are operational in theater. The program is also addressing challenges to increase reliability, availability, maintainability, and effective time-on-station metrics for the system. In addition to commenting on this assessment, the Air Force provided technical comments, which we incorporated where appropriate.



GAO Response

In January 2012, DOD announced its plan to terminate the Global Hawk block 30 system in fiscal year 2013, due to the high cost associated with the program.



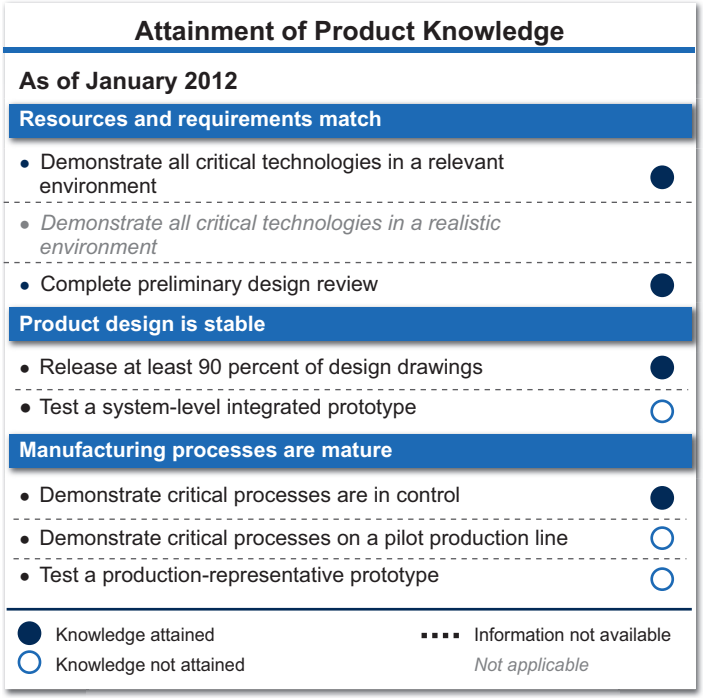
2218 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Global Positioning System (GPS) III

The Air Force's Global Positioning System (GPS) III program plans to develop and field a new generation of satellites to supplement and eventually replace GPS satellites currently in use. Other programs will develop the ground system and user equipment. GPS III will be developed incrementally. We assessed the first increment, which intends to provide capabilities such as a stronger military navigation signal to improve jamming resistance and a new civilian signal that will be interoperable with foreign satellite navigation systems.

Source: U.S. Air Force.

Program Essentials



Prime contractor: Lockheed Martin
Program office: El Segundo, CA
Funding needed to complete:
- R&D: $924.6 million
- Procurement: $1,435.0 million
- Total funding: $2,359.6 million
- Procurement quantity: 6

Program Performance (fiscal year 2012 dollars in millions)

	As of 05/2008	Latest 08/2011	Percent change
Research and development cost	$2,524.2	$2,694.8	6.8
Procurement cost	$1,417.2	$1,515.8	7.0
Total program cost	$3,941.4	$4,210.6	6.8
Program unit cost	$492.672	$526.323	6.8
Total quantities	8	8	0.0
Acquisition cycle time (months)	NA	NA	NA

We could not calculate acquisition cycle times for the first increment of the GPS III program because initial operational capability will not occur until satellites from a future increment are fielded.

The GPS III entered production in January 2011 with mature technologies and some of the knowledge needed to ensure the system would work as intended and could be manufactured efficiently. A complete satellite was not tested prior to the production decision, but the program is developing prototypes of the spacecraft and payload to prove out production processes and identify and solve issues prior to integrating and testing the first space vehicle. The GPS III is experiencing cost growth and the contractor is behind schedule, but the program does not expect these delays to affect the launch of the first satellite. There are risks to the program launching some satellites as planned. The GPS III ground control system is not scheduled for delivery until 15 months after the first scheduled launch and it is unclear whether an interim capability will be delivered in time.

2219 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

GPS III Program

Technology and Design Maturity

The GPS III program's critical technologies are mature and its design is stable. The critical technologies changed as the program developed its design, but all eight current technologies have been demonstrated in a relevant environment. The GPS program office reported that the number of design changes since its design review has been much less than anticipated. In addition, according to the program office, some of the system's flight software has completed qualification testing and other software deliverables are on schedule.

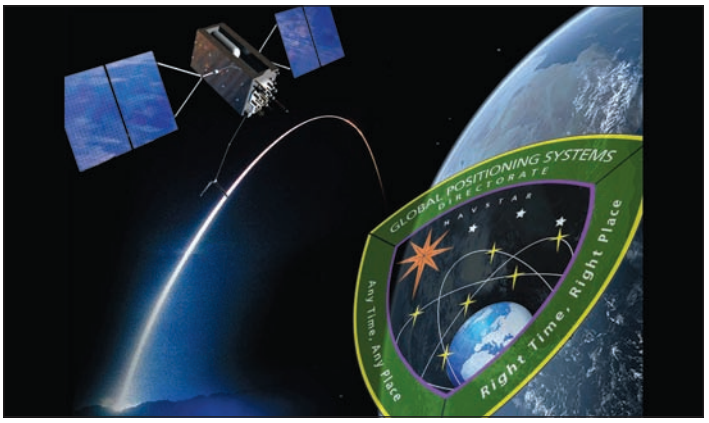
Production Maturity

The GPS III program captured some of the knowledge needed to ensure the system would work as intended and could be manufactured efficiently before its January 2011 production decision. In 2011, the program office reported a level of manufacturing process maturity that indicated that its processes were in control when a production decision was made. A complete GPS III satellite was not tested prior to the production decision, but the program is developing prototypes of the spacecraft and payload to prove out production processes and identify and solve issues prior to integrating and testing the first space vehicle.

Other Program Issues

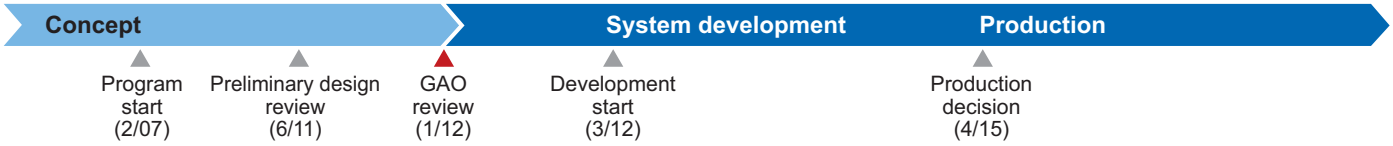
The GPS III program has adopted several practices to reduce program risk. It has maintained stable requirements and is being managed using a "back to basics" approach, which features rigorous systems engineering, use of military specifications and standards, and an incremental approach to providing capability. However, the GPS III program is currently experiencing cost growth and the contractor is behind schedule. In November 2011, the contractor's estimated cost at completion for the development and production of the first two satellites was over $1.4 billion or 18 percent greater than originally estimated; the program office estimated the cost to be about $1.6 billion. The Air Force has cited multiple reasons for the projected contract cost increases including reductions in the program's production rate; greater than expected efforts to produce engineering products compliant with more stringent parts, materials, and radiation testing requirements; test equipment delays; and inefficiencies in the development of both the navigation and communication payload and satellite bus. The contractor is also behind in completing some tasks, but the program does not expect these delays to affect the launch of the first satellite.

The GPS directorate has taken steps to mitigate GPS III's dependence on the development schedule for the next-generation GPS ground control system, the OCX, which is being managed as a separate major defense acquisition program, but some GPS III launches could be affected if OCX is delayed. The contractor plans to deliver GPS OCX Block I in August 2015—15 months after the first planned GPS III satellite launch. The GPS directorate is funding the development of a launch and checkout system that will provide an earlier command and control capability for the first GPS III satellite, but it unclear when this system will be delivered. According to GPS directorate officials, this system will not enable the new capabilities offered by GPS III satellites, including a jam-resistant military signal and three new civil signals. GPS program officials stated previously that they would prefer not to launch a second satellite until the capabilities of the first one are fully tested. Although the Air Force has slowed its planned pace of launches for GPS III so that there should not be a rapid succession of launches within 2 years of the first GPS III launch, further delays in the OCX program could still affect the dates of some GPS III launches.



Program Office Comments

In commenting on a draft of this assessment, the GPS III program provided technical comments, which were incorporated as appropriate.



2220 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

GPS III OCX Ground Control Segment

The Air Force's next-generation GPS control segment, referred to as OCX, will provide command, control, and mission support for the GPS Block II and III satellites. OCX is expected to ensure reliable and secure delivery of position and timing information to GPS military and civilian users. The Air Force plans to develop OCX in four blocks, with each block delivering upgrades as they become available. We assessed the first block, which will support the operation of GPS Block II and Block III satellites.

Program Essentials

Prime contractor: Raytheon
Program office: El Segundo, CA
Funding FY12 to FY16:
R&D: $1,583.9 million
Procurement: $35.6 million
Total funding: $1,619.5 million
Procurement quantity: NA

Program Performance (fiscal year 2012 dollars in millions)

	As of	Latest 09/2011	Percent change
Research and development cost	NA	$2,538.5	NA
Procurement cost	NA	$35.6	NA
Total program cost	NA	$2,574.1	NA
Program unit cost	NA	NA	NA
Total quantities	NA	NA	NA
Acquisition cycle time (months)	NA	NA	NA

Table includes costs from program inception through fiscal year 2016.

GPS OCX plans to enter system development in March 2012 with some of the recommended knowledge about its requirements and technologies. The program held a preliminary design review in June 2011 and its critical technologies are nearing maturity. The Air Force awarded a cost-reimbursement contract for Blocks I and II in February 2010 before it received approval to formally enter system development. The first two software packages have been completed, but the complexity of the software development effort has proven challenging. The GPS OCX will not be fielded in time to support the first GPS III satellite, which is scheduled for launch in May 2014. As a result, the GPS directorate is funding an effort to provide an earlier command and control capability, but this system will not enable the new capabilities offered by that satellite.

Attainment of Product Knowledge

2221 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

GPS OCX Program

Technology Maturity

According to program officials, the GPS OCX plans to enter system development in March 2012 with its 14 critical technologies nearing maturity. However, these technologies will not be fully tested and demonstrated in a realistic environment until the program makes its production decision. The program held a preliminary design review in June 2011, which was completed in August 2011, and has addressed most of the issues that were identified during the review. The remaining issues, which the program deems low risk, relate to better defining certain requirements, including those for reliability. The program office developed mitigation plans to address these issues and an independent review team approved the plans as well as the design and architecture of the OCX system.

Other Program Issues

The complexity of the GPS OCX software development effort has proven challenging and two current software efforts were started behind schedule. According to the program office, the GPS OCX contract requires the delivery of six Block I software iterations by February 2015 and two Block II software iterations by March 2016. According to program officials, the first and second Block I iterations were completed on schedule; however, the third iteration was started later than planned and is expected to be completed later than originally scheduled as well. Preliminary work has begun on the fourth iteration, which is also running behind schedule. The primary reasons for the delay in the delivery of the third iteration, and the late start of the fourth iteration, were the difficulty of developing new code, as well as the contractor's focus on getting through the preliminary design review process, which, according to program officials, required more work than the contractor originally anticipated.

According to program officials, because of the complexity of the GPS OCX software, the program has instituted a rigorous testing process to identify and address defects early in each iteration. The program expects that this process will reduce the number of defects discovered in higher-level integration and testing, which can be more costly to resolve. This testing approach has already identified a number of defects in the early iterations, and the number of defects that are being found during integration testing has been lower than expected.

The contractor plans to deliver GPS OCX Block I in August 2015—15 months after the first planned GPS III satellite launch. As a result, the GPS directorate is funding the development of a launch and checkout system that will provide an earlier launch and command and control capability for the first GPS III satellite. According to GPS directorate officials, this system will not enable the new capabilities offered by GPS III satellites, including a jam-resistant military signal and three new civil signals. The program released a request for proposal for the launch and checkout system in April 2011 and awarded the effort in December 2011. The launch and checkout system is expected to cost about $30 million through 2015. Any delay in the delivery of the launch and checkout system could potentially cause the Air Force to delay the launch of the first GPS III satellite.

Program Office Comments

The Air Force provided technical comments, which were incorporated as appropriate.

2222 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Gray Eagle Unmanned Aircraft System

The Army's MQ-1C Gray Eagle will perform reconnaissance, surveillance, target acquisition, and attack missions either alone or with other platforms such as the Longbow Apache helicopter. In 2010, the Army changed the number of Gray Eagle systems from 13 company-sized units with 12 aircraft to 31 platoons with 4 aircraft. Each platoon will also include payloads, data terminals, and other ground support equipment. The program consists of block 1 systems and two less-capable Quick Reaction Capability systems. We assessed block 1.

Source: General Atomics Aeronautical Systems, Inc.

Program Essentials

Prime contractor: General Atomics Aeronautical Systems, Inc.
Program office: Redstone Arsenal, AL
Funding needed to complete:
R&D: $226.1 million
Procurement: $2,089.0 million
Total funding: $3,006.9 million
Procurement quantity: 16

Program Performance (fiscal year 2012 dollars in millions)

	As of 04/2005	Latest 08/2011	Percent change
Research and development cost	$344.9	$946.2	174.4
Procurement cost	$670.4	$3,400.2	407.2
Total program cost	$1,015.2	$5,158.9	408.2
Program unit cost	$203.046	$166.416	-18.0
Total quantities	5	31	520.0
Acquisition cycle time (months)	50	TBD	NA

Total quantities include 31 platoon sets with 4 aircraft each. The program will also buy 21 aircraft to replace those lost through attrition and 7 training aircraft, for a total of 152.

The Gray Eagle program began production in February 2010 with three of its five critical technologies not yet mature and manufacturing processes that still exhibited production risks. The program has demonstrated two of those technologies in a realistic environment and expects to demonstrate the third one in fiscal year 2012. A March 2011 aircraft accident resulted in hardware and software changes. Some of the changes required retrofits to systems already produced. As a result of the accident, the Army delayed the program's initial operational test and evaluation and full-rate production decision. To avoid a production break, the Army plans to award a third low-rate production contract in May 2012. It now plans to procure more than half of the total aircraft before the system is fully tested.

2223 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Gray Eagle Program

Technology Maturity

The Gray Eagle entered production in February 2010 without all five of its critical technologies mature. An Army technology readiness assessment, which was approved by the Office of the Director, Defense Research and Engineering, in 2009, concluded that three of those technologies—automatic take-off and landing, manned-unmanned teaming, and the tactical common data link—had not been fully demonstrated in an operational environment. According to the program office, the automatic take-off and landing system is now mature, and manned-unmanned teaming was demonstrated in 2011 with an Apache helicopter controlling Gray Eagle. However, the tactical common data link is still not fully mature. The program office stated that the data link encryption capability was successfully tested in 2011, but its air data relay capability has been deferred until fiscal year 2012.

Design Maturity

The program office believes the Gray Eagle design is currently stable; however, the program has experienced a significant increase in design drawings due to issues identified during testing and other technical changes. The program has made modifications to the system's software and hardware following a March 2011 accident and system testing. The Army has installed the software changes on aircraft that were in production as well as fielded aircraft, and plans to make hardware changes that include redesigning the aircraft's rudders. The program office stated that it does not yet know the cost or schedule for completing these modifications.

Production Maturity

Gray Eagle began production in February 2010 with manufacturing processes that had been demonstrated on a pilot production line, but still exhibited production risks. An independent Army assessment of the program's production readiness in 2009 stated that manufacturing process maturity was satisfactory and manufacturing infrastructure met or exceeded requirements for low-rate initial production. It is unclear whether the Army expects planned hardware redesigns to affect the maturity of the Gray Eagle's production processes. If tooling or other manufacturing changes are necessary, its production processes could be affected.

Other Program Issues

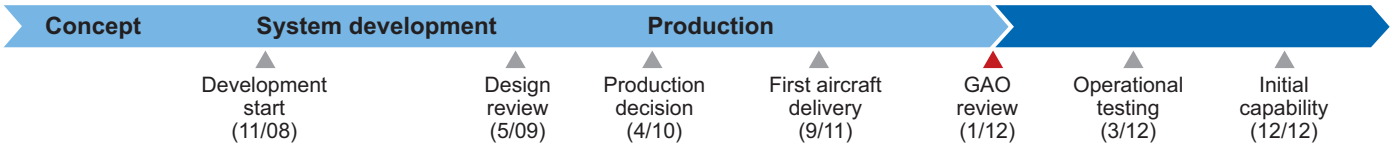
The March 2011 accident involving an MQ-1C in testing has delayed several key program events. According to the program office, the accident investigation made it difficult to accumulate flight hours and conduct the soldier training needed to support initial operational test and evaluation in October 2011. The Army now plans to start operational testing in August 2012. As a result of the delay in operational testing, the program's full-rate production decision was postponed from August 2012 to March 2013. The Army has already awarded two low-rate production contracts in 2010 and 2011 for 55 aircraft. To avoid a break in production, the Army is planning to seek approval to award a third low-rate contract for 29 aircraft in May 2012. Based on the current program schedule, the Army will procure more than half of the total planned aircraft before the system's operational effectiveness and suitability is fully tested during initial operational test and evaluation.

Program Office Comments

In commenting on a draft of this assessment, the program office stated the Gray Eagle baseline design is mature. The program also indicated that changes to the system's software and hardware are planned improvements as new payloads and capabilities are integrated. Additionally, the program office noted that the automatic take-off and landing system and tactical common data link have been demonstrated because deployed units have been operating with these technologies. The program anticipates that the data link's air data relay capability will be operationally tested in August 2012 and manned-unmanned teaming with an Apache Block III helicopter will be operationally tested in March 2012. The program also provided technical comments, which were incorporated as appropriate.

GAO Response

The program office considers the Gray Eagle baseline design mature, but the tactical common data link's full capabilities have not yet been tested. Additionally, as the program office noted, the Army will be modifying the aircraft tail rudder and elevator. Until the data link is fully mature and all design changes have been developed and incorporated, the program's cost and schedule remain at risk.

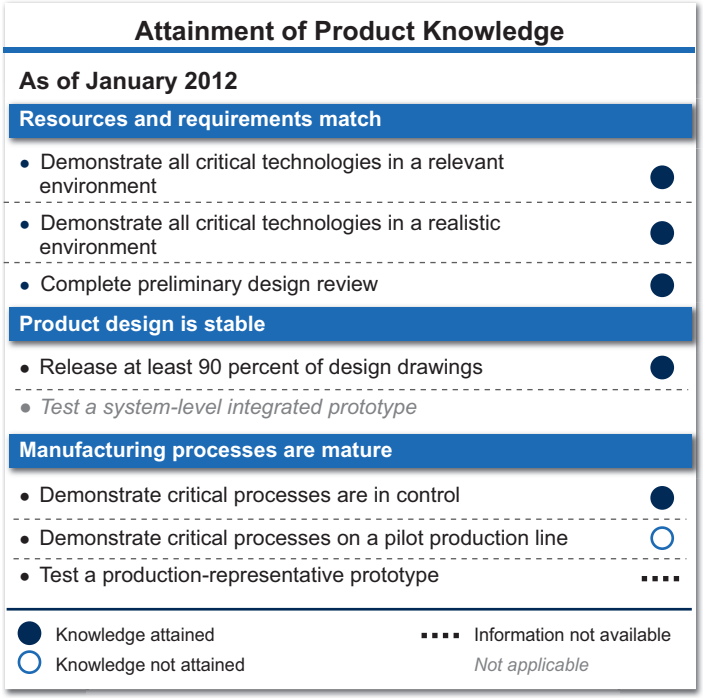


2224 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

HC/MC-130 Recapitalization Program

The Air Force's HC/MC-130 Recapitalization program will replace aging Air Force HC-130P/N and Air Force Special Operations Command MC-130E/P/W/H aircraft with a multimission tactical aircraft that is based on the KC-130J platform. The primary mission of HC/MC-130J aircraft will be to provide aerial refueling. It will also position, supply, resupply, and recover specialized tactical ground units. The program includes a base configuration and three increments that provide additional capabilities.

Source: Lockheed Martin.



Program Essentials

Prime contractor: Lockheed Martin
Program office: Wright-Patterson AFB, OH
Funding needed to complete:
R&D: $82.6 million
Procurement: $9,532.4 million
Total funding: $9,812.7 million
Procurement quantity: 91

Program Performance (fiscal year 2012 dollars in millions)

	As of 03/2010	Latest 12/2010	Percent change
Research and development cost	$153.2	$152.8	-0.3
Procurement cost	$7,699.3	$12,621.9	63.9
Total program cost	$8,364.2	$13,090.8	56.5
Program unit cost	$113.029	$107.302	-5.1
Total quantities	74	122	64.9
Acquisition cycle time (months)	NA	NA	NA

The HC/MC-130J program entered production in April 2010 with mature critical technologies, a stable design, and manufacturing processes that were in control. The HC/MC-130J design is derived from the KC-130J aerial refueling tanker, and shares many of the same technologies; the system that allows it to receive fuel in-flight and the electro-optical/infrared turret mount are unique. According to program officials, the HC/MC-130J has completed developmental testing and is scheduled to enter operational testing in March 2012. Operational testing will be conducted with increment 1–configured aircraft, which make up 10 of the planned total 122 aircraft. The program plans limited testing for increment 2, which will primarily focus on the integration of Large Aircraft Infrared Counter Measures (LAIRCM). Twenty-five increment 2 aircraft are already under contract.

2225 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

HC/MC-130 Recapitalization Program

Technology Maturity

The HC/MC-130 Recapitalization program entered system development in November 2008 with both of its critical technologies mature. Several of the HC/MC-130J's technologies are common with the KC-130J, including the rotor wing aerial refueling system. According to program officials, the two HC/MC-130J critical technologies—the electro-optical/infrared turret mount and the universal aerial refueling receptacle slipway installation (UARRSI)—are unique to the aircraft. The UARRSI allows the HC/MC-130J to receive fuel in-flight, extending the range of the aircraft.

Design Maturity

The HC/MC-130J design is stable and over 90 percent of its drawings were released by the time the program held its critical design review in May 2009. The HC/MC-130J is about 90 percent common with the C-130J, which has contributed to the aircraft's design maturity and stability.

Production Maturity

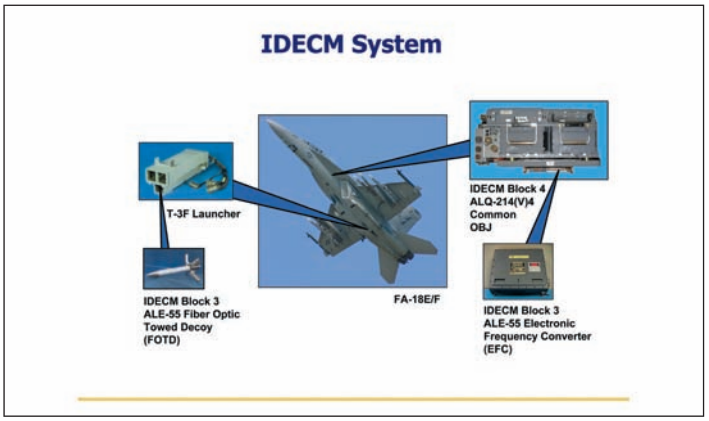
The HC/MC-130J program entered production in April 2010 with manufacturing processes that were in control. In addition, program officials told us that rework rates for repairs and defects is trending downward and have been within the expected range. A combination of a labor force unaccustomed to the aircraft and a ramp-up in production contributed to the rework rates—factors common across the C-130J platform.

Other Program Issues

According to program officials, the HC/MC-130J successfully completed developmental testing on base-configured aircraft in August 2011, slightly ahead of schedule. Operational testing—scheduled to begin in March 2012—will be conducted on increment 1–configured aircraft, which make up 10 of the planned total 122 aircraft in the program. Program officials stated that the Office of the Director, Operational Test and Evaluation, certified increment 1 aircraft as being production-representative, which would make it appropriate for use in operational testing. Program officials noted that several software- and hardware-related watch items identified during contractor testing must be resolved prior to the start of operational testing; however, they described these items as relatively minor and easily correctable.

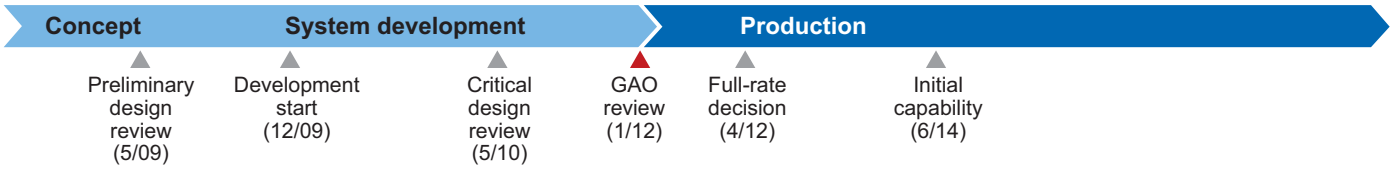
According to program officials, there will be limited testing of increment 2–configured aircraft. This testing will be focused primarily on the integration of the LAIRCM system. Although the basic LAIRCM system is in production, recently concluded testing on LAIRCM's upgraded missile warning system revealed deficiencies that may affect integration with HC/MC-130J. The HC/MC-130J program includes 40 increment 2 aircraft, 25 of which have already been placed under contract.

Due to the extended budget impasse for fiscal year 2011, the program office stated that it did not have sufficient authority under the continuing resolution to award a contract for nine aircraft as planned. In order to avoid a production break, the Air Force redirected approximately $500 million from other programs for the procurement of these aircraft. According to program offices, had an award not been made before the contractor's proposal expired in May 2011 the program would have been delayed by more than a year.



Program Office Comments

In commenting on a draft of this assessment, the Air Force provided technical comments, which were incorporated as appropriate.



2226 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Integrated Defensive Electronic Countermeasures (IDECM) Block 4

The Navy's IDECM is a radio-frequency, self-protection electronic countermeasure to improve the survivability of F/A-18 aircraft against guided threats during air-to-ground/surface and air-to-air missions. IDECM consists of onboard components that receive and process radar signals and onboard and offboard jammers. IDECM is being developed incrementally; each block improves its jamming or decoy capabilities. The Navy has fielded three IDECM blocks; block 4 will extend onboard jamming capabilities for F/A-18C/D aircraft. We assessed block 4.

Funding needed to complete:
- R&D: $121.4 million
- Procurement: $569.5 million
- Total funding: $690.9 million
- Procurement quantity: 190

Program Performance (fiscal year 2012 dollars in millions)

	As of 06/2008	Latest 10/2011	Percent change
Research and development cost	$220.2	$252.0	14.5
Procurement cost	$474.2	$569.5	20.1
Total program cost	$694.4	$821.5	18.3
Program unit cost	$4.340	$4.324	-0.4
Total quantities	160	190	18.8
Acquisition cycle time (months)	59	54	-8.5

IDECM block 4 expects to begin production in April 2012 with mature technologies and a stable design. Block 4 primarily replaces the previous IDECM onboard jammer with a lightweight repackaged version. There is some concurrency risk on the program, which could drive costly design changes or retrofits if the redesigned jammer does not perform as intended. The Navy has no plans for low-rate initial production and will proceed to full-rate production before it completes ground and flight testing. Program officials stated that this concurrency is necessary in order to maintain the production line from block 3 to block 4 and to meet the June 2014 initial operational capability date. In addition, program officials noted that block 4 production will be limited initially to 19 units and the production rate will only increase once testing is completed.

2227 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

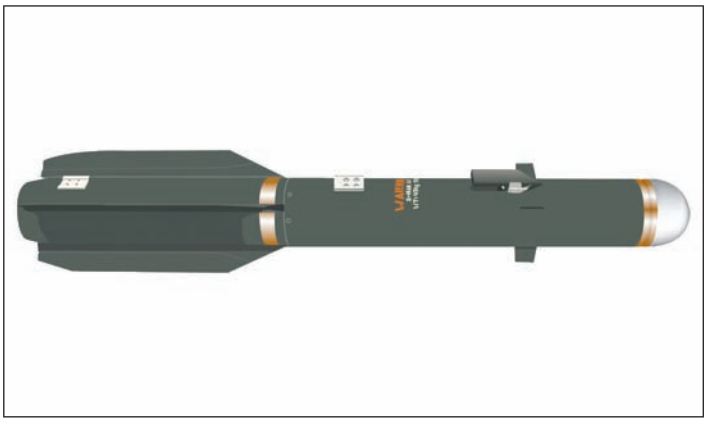
IDECM Block 4 Program

Technology Maturity

IDECM block 4 began system development in 2009 as an engineering change proposal to the existing block 3 onboard jammer. Block 4 will reconfigure the ALQ-214 (V)3 onboard jammer, currently only installed in the F/A-18E/F aircraft, to a common configuration—ALQ-214 (V)4—to be installed on F/A-18C/D and F/A-18E/F aircraft. In April 2009, a technology readiness assessment concluded that there were no critical technologies in the ALQ-214 (V)4 and that the system was based on mature technologies.

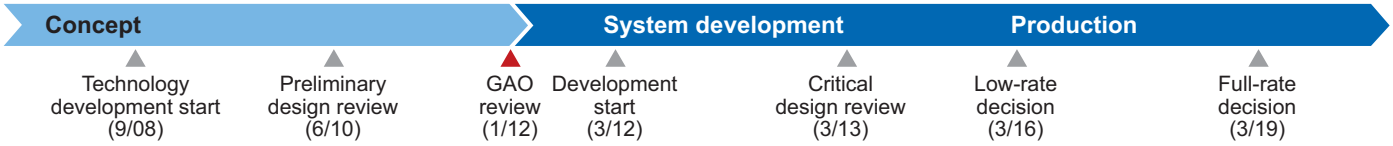
Design and Production Maturity

IDECM block 4's design is stable; however, there is still risk in the IDECM block 4 program because it expects to begin production in April 2012 before developmental testing is completed. The block 4 onboard jammer is a redesign of the jammer used in earlier blocks. This redesign was driven by the need to reduce weight in order to accommodate the IDECM onboard system on F/A-18C/D aircraft. The block 4 onboard jammer will perform the same function as found in IDECM blocks 2 and 3, but with a different form. The Navy expects to transition from block 3 production to block 4 production before the system completes ground and flight testing. The program will proceed directly into full-rate production. This concurrent production and testing strategy could drive costly design changes or retrofits, or both, to units in production if the redesigned jammer does not perform as intended. Officials stated that this concurrency is necessary in order to maintain the production line and to meet the June 2014 initial operational capability date for block 4. To mitigate the concurrency risk, Navy officials stated that block 4 production will be limited to 19 systems in 2012, with production rates increasing to as many as 40 systems per year following completion of testing.



Program Office Comments

In commenting on a draft of this assessment, the Navy stated that the block 4 configuration will begin full-rate production in fiscal year 2012. The IDECM program office believes the cost risks associated with this production decision are low. While the production line transition to the new block 4 configuration will occur prior to the completion of flight testing in 2013, all testing will be completed prior to delivery of the production hardware and fleet introduction in 2014. To date, 13 systems have been delivered and utilized in developmental testing. In addition, the Navy noted that the firm fixed-price production contract requires the contractor to deliver assets that incorporate any design changes identified during testing. According to the Navy, the contractor would be required to retrofit changes into any assets already built at no additional cost to the government. The Navy also noted that the increase in the block 4 research and development cost estimate is associated with an additional requirement for an improved jamming capability against advanced threats. The increase in the procurement cost estimate is associated with a requirement for additional quantities.



2228 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Joint Air-to-Ground Missile (JAGM)

The Joint Air-to-Ground Missile is a joint Army/Navy program with Marine Corps participation. The missile will be air-launched from helicopters and fixed-wing aircraft and designed to target tanks; light armored vehicles; missile launchers; command, control, and communications vehicles; bunkers; and buildings. It is intended to provide line-of-sight and beyond line-of-sight capabilities and can be deployed in a fire-and-forget mode or a precision attack mode. JAGM will replace Hellfire, Maverick, and air-launched TOW missiles.

JAGM is expected to enter system development in 2012 with some of the recommended knowledge about its technology and requirements; however, the program's future is uncertain because of concerns about its affordability. According to the program office, the program held a preliminary design review in June 2010 and its five critical technologies are nearing maturity. However, an independent technology readiness assessment indicated that at least one technology has not reached this level of maturity. The program office incorporated a provision in the request for proposal for the system development contract that may mitigate the technology risk by requiring both competing contractors to submit two rocket motor designs. According to program officials, the program plans to award a contract in March 2012, despite ongoing uncertainty regarding the future of the program.

2229 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JAGM Program

Technology Maturity

According to the program office, JAGM's five critical technologies are expected to be nearing maturity and demonstrated in a relevant environment before a decision is made to start system development. The critical technologies include a multimode seeker for increased countermeasure resistance, boost-sustain propulsion for increased standoff range, a multipurpose warhead for increased lethality, an inertial measurement unit for improved navigation and flight control, and guidance and control software. However, an independent technology readiness assessment indicated at least one of these technologies has not reached this level of maturity. We cannot identify the assessed maturity levels of individual technologies because the program is currently conducting a competition for its system development contract. According to program officials, the technology readiness assessment will be updated prior to development start based on contractors' proposals.

The program office incorporated a provision in the request for proposal that may mitigate some of the program's technology risk by requiring both competing contractors to submit two rocket motor designs. The government also planned to complete environmental and safety tests using eight rocket motors from each contractor during the technology development phase. The tests were intended to examine the rocket motors under the extremes of the expected operational environment to ensure they can perform safely and effectively. The tests were expected to be complete by December 2011.

Other Program Issues

The future of the JAGM program is uncertain because of concerns about its affordability. Army officials have stated that the service might not be able to afford JAGM, despite having a validated requirement for it. According to Army officials, the Hellfire missile, which JAGM is intended to replace, has been performing well in combat operations, and given budget constraints, the Army may prefer to extend its use indefinitely rather than pursue JAGM as a next generation solution. However, according to program officials, an analysis of alternatives completed in August 2011 indicated that JAGM is the most cost-effective solution to address warfighter needs. Program officials stated that the program plans to continue executing to its fiscal year 2012 budget plan. The Army will continue to field Hellfire missiles to meet the needs of the warfighter, while the Navy will rely on both Maverick and Hellfire missiles until the future of JAGM is determined.

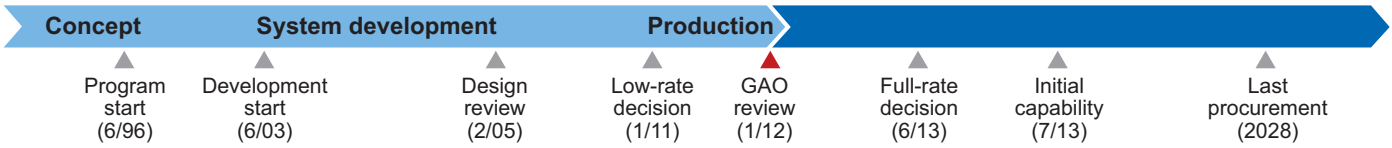
According to program officials, the program plans to award its system development contract in March 2012, notwithstanding the uncertainty regarding JAGM's future. The program has received approval to conduct a limited competition between its two technology development contractors. It had intended to award the contract in December 2010; however, the release of the request for proposal was delayed until April 2011 because the program's acquisition strategy and requirements needed to be updated to reflect the cancellation of the Armed Reconnaissance Helicopter, the addition of the OH-58 Kiowa as a replacement platform, and new guidance on affordability.

Program Office Comments

The JAGM program office concurred with this assessment and provided technical comments, which were incorporated as appropriate.

GAO Response

After our assessment was completed, the President's Budget for Fiscal Year 2013 extended JAGM's technology development phase by 27 months to address affordability issues and reduce risk prior to system development.



2230 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Joint Air-to-Surface Standoff Missile Extended Range (JASSM-ER)

The Air Force's JASSM-ER program plans to field a next-generation cruise missile capable of destroying the enemy's war-sustaining capability from outside its air defenses. JASSM-ER missiles are low-observable, subsonic, and have a range greater than 500 miles. They provide both fighter and bomber crews the ability to strike heavily defended targets early in a campaign. JASSM-ER is a follow-on program to the JASSM baseline program. The two missiles' hardware is 70 percent common and their software is 95 percent common.

Acquisition cycle time (months)	NA	NA	NA

JASSM-ER was approved to begin production in January 2011 with mature critical technologies, a stable design, and production processes that had been demonstrated, but were not in control. The JASSM-ER appears to have overcome past reliability issues and, according to program officials, the missile's design has been proven in flight testing. However, an engine oil leak was discovered in December 2011 that required the program office to return 13 engines to the manufacturer for corrective action, causing a 3- to 4-month delay in operational testing. In response to a warfighter request, the program is considering a significant increase in production rates starting in 2016. The program will need additional funding in the short term to increase production rates, but doing so could shorten production by 3 years and save about $521 million.

2231 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JASSM-ER Program

Technology Maturity

According to the program office, the JASSM-ER's five critical technologies—the engine lube system, engine system, fuse, low observable features, and global positioning system—are mature and have been tested in a realistic environment using a production-representative test missile.

Design Maturity

The JASSM-ER's design appears stable and the program seems to have overcome past reliability issues. The number of JASSM-ER configuration changes has decreased over time and, according to the program office, there was only 1 major configuration change and 16 minor configuration changes in the last year, 1 of which was related to the missile's reliability. In addition, according to program officials, the missile's design has been proven in testing; 10 out of 11 flight tests have been successful.

Despite the JASSM-ER's initial operational test success, testing has been put on hold because of problems with the missile's engine. An engine oil leak was discovered in December 2011 and all engines used in the operational test program were returned to the manufacturer to have corrective actions installed. These corrective actions will cause a 3- to 4-month delay in operational testing. However, program officials are optimistic that the program's full-rate production decision will not be affected because the full-rate decision is not scheduled until June 2013.

Production Maturity

The JASSM-ER entered production in January 2011 with processes that had been demonstrated, but were not in control. Prior to the production decision, the Air Force assessed that the JASSM-ER's manufacturing readiness was at the level recommended by DOD guidance for the start of low-rate production. However, the program's manufacturing readiness level did not indicate that its production processes were in statistical control. The program does not collect data on its critical manufacturing processes because the program was initiated using a total system performance responsibility arrangement, but the contractor does share some manufacturing data with the program office to prove it is meeting the missile's specification requirements. The contractor has implemented a process verification program with suppliers for the baseline missile to ensure that proper production processes are being followed. Program officials stated that the process verification program is not a contractual requirement, but rather a technique the contractor considers a best practice. According to program officials, process verification will also be used on the JASSM-ER.

Other Program Issues

Program officials stated that a combatant command has requested that more JASSM-ER missiles be delivered earlier than planned. To accommodate this request, program officials explained that JASSM-ER is scheduled to receive additional funding starting in fiscal year 2016 to pay for an additional 150 missiles per year. This rate increase may allow the program to shorten the production schedule by 3 years and save about $521 million. To attain these savings, program officials said the missile will need to reach its economic order quantity of 360 missiles per year by 2016 and continue at that production rate through the end of its production schedule.

Program Office Comments

In commenting on a draft of this assessment, Air Force officials stated the JASSM-ER engine oil leak anomalies were identified in the production facility during missile assembly. Program office and Air Force testers jointly determined that the most-prudent course of action would be to delay operational testing until the issue could be solved. A root cause and corrective action have been identified and all operational testing and future production missiles will include the corrective actions. Operational testing is expected to resume in June 2012, with no risk to accomplishing full-rate production in June 2013. The Air Force also provided technical comments, which were incorporated as appropriate.

Acquisition cycle time (months)	48	50	4.2

The JHSV program began lead-ship fabrication in December 2009 with its critical technologies mature, but without a stable design. Only 9 of the ship's 44 design zones were complete in the three-dimensional product model. According to program officials, all 44 design zones were completed 9 months later in September 2010. The lead ship was launched in September 2011; however, according to the shipbuilder's data, the cost and schedule of the ship have been affected by an increase in the ship's weight. According to the Navy, delivery of the lead ship was to occur in December 2011 and will now occur in the spring of 2012. According to program officials, the Navy is reviewing the number of JHSVs required for future operations, and program quantities could change.

2233 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JHSV Program

Technology and Design Maturity

The JHSV program began lead-ship fabrication in December 2009 with all 18 of its critical technologies mature and demonstrated in a realistic environment, but without a stable design. Only 9 of the ship's 44 three-dimensional design zones were complete. This level of maturity falls short of GAO's best practices, which call for achieving a complete and stable three-dimensional product model before construction begins to minimize the risk of design changes and the subsequent costly rework and out-of-sequence work these changes can drive. According to program officials, all 44 zones were completed in September 2010, 9 months after fabrication began. However, as of August 2011, the American Bureau of Shipping had not yet completed acceptance of the JHSV design because some drawings that support functional and structural design were still outstanding.

Production Maturity

According to program officials, the JHSV program does not use critical manufacturing processes to measure production maturity. Instead, it monitors quality metrics of specific trades such as welding, monitors the contractor's earned value management data, and measures the current schedule against the production schedule. Additionally, the program demonstrated its manufacturing processes by building one of the ship's modules in the shipbuilder's new manufacturing facility. The lead ship was launched in September 2011 and, according to program officials, was 90 percent complete at that time. Construction of the second ship began September 2010, and was about 25 percent complete as of August 2011. According to shipbuilder data, a significant increase in the weight of the ship has negatively affected its construction cost and schedule by requiring additional material, production and engineering work, and design efforts. According to the Navy, delivery of the lead ship has been delayed and will now occur in the spring of 2012.

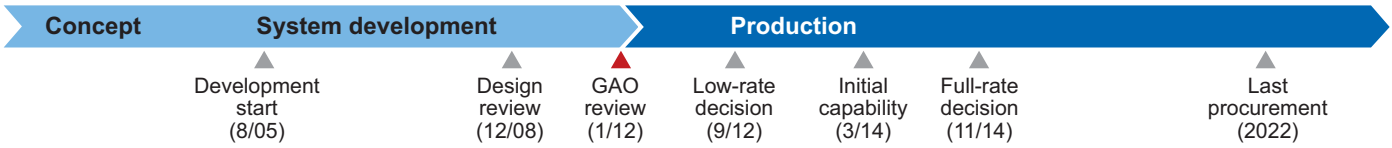
Austal USA, the shipyard that is constructing JHSV, is also building one version of the Littoral Combat Ship. According to officials, as a result of corrosion found in the water jet propulsion area of that ship, the JHSV program has conducted corrosion reviews and is applying the lessons learned from the Littoral Combat Ship to mitigate the potential for corrosion.

Other Program Issues

As a result of discussions with the Army in December 2010, the Navy assumed the role of life cycle manager and will operate all current and future JHSVs, including the five planned for procurement by the Army, on all missions. According to program officials, a requirements study is intended to determine the total quantity of JHSVs needed to support operations for both military services. The December 2010 selected acquisition report for the JHSV program lists a total quantity of 18 ships, including the 5 Army vessels; however, the Navy's May 2011 30-year shipbuilding plan lists a total of 21 ships.

Program Office Comments

In commenting on a draft of this assessment, the Navy stated that the JHSV design is based on existing commercial platforms, and the design was 90 percent complete at the start of construction. The Navy further stated that GAO's best practices notwithstanding, sufficient production information from the two-dimensional design drawings and three-dimensional model has been developed to support production. Significant production risk has been avoided by implementing proven commercial production design and technology, ensuring stable requirements, minimizing change, and through pursuit of cost reduction and efficiency. In addition, the President's Budget for Fiscal Year 2013 reduced the total number of ships to be procured to 10. The Navy also provided technical comments, which were accounted for as appropriate.



2234 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Joint Land Attack Cruise Missile Defense Elevated Netted Sensor System (JLENS)

The Army's JLENS is designed to provide over-the-horizon detection and tracking of land-attack cruise missiles and other targets. The Army is developing JLENS in two spirals. Spiral 1 is complete and served as a test bed to demonstrate the concept. Spiral 2 will utilize two aerostats with advanced sensors for surveillance and tracking, as well as mobile mooring stations, communication payloads, and processing stations. JLENS will provide surveillance and targeting support to other systems, such as Patriot and Standard Missile-6. We assessed Spiral 2.

Acquisition cycle time (months)	97	103	6.2

According to program officials, JLENS will enter production in September 2012 with mature technologies, a stable design, and proven production processes. Early problems with the software for the system's fire control radar—a critical technology—delayed the program's entry into developmental test and put the production decision date at risk. The JLENS design appears stable and some key production planning and test activities are complete, but the potential for design changes remains until the maturity of key components has been demonstrated and they have been successfully integrated and tested. In September 2010, an aerostat accident resulted in the loss of one of the JLENS platforms. The accident, as well as recent system integration challenges, delayed the program's production decision by 6 months and resulted in a Nunn-McCurdy unit-cost breach of the significant threshold.

2235 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JLENS Program

Technology Maturity

JLENS entered system development in August 2005 with only one of its five critical technologies mature. Two additional technologies—the communications processing group and platform—are now mature, and the program expects to demonstrate the fire control radar and surveillance radar in a realistic environment before production begins. Many of the JLENS radar technologies have legacy components. However, sensor software items related to signal processing, timing, and control, as well as element measurement, are not yet mature and problems have surfaced in software verification testing. Program officials said a decision to use newer technology introduced unexpected problems that could delay demonstration tests and the integration of both the radars' components.

Design Maturity

The JLENS design appears stable, but the potential for design changes will remain until key JLENS components have been integrated and tested. The recently resolved software problems associated with the fire control radar indicate that the system may still be immature and is at risk of not meeting system performance requirements. These issues could further delay planned tests, as well as the program's production decision. Although the program has had some success, including the first flight demonstration of the aerostat in August 2009, the program must still complete a series of tests integrating the sensors and processing station. An aerostat accident in September 2010 resulted in only minor damage to the mobile mooring station, but the aerostat and associated avionics and electronics were destroyed and important tests to assess the maturity of the system's design had to be postponed. In addition, the Army deployed one aerostat and mobile mooring station for combatant command exercises for the warfighter, which removed an important test asset from the program.

Production Maturity

The JLENS program projects that JLENS will enter production in September 2012 with all 15 of its critical manufacturing processes mature and stable. According to the program office, 12 of the program's critical manufacturing processes are currently in control. The JLENS program has also completed a number of key activities that are essential to effective production management, including updating its manufacturing plan and addressing areas such as supplier capabilities and risks, cost, quality control, materials, producibility, and workforce skills.

Other Program Issues

The JLENS program is working to address several risks that could affect the program's cost, schedule, and performance. First, due to the aerostat accident, JLENS program officials estimate a program effect of $8 million to $10 million. Second, schedule effects resulting from resolution of problems with the fire control radar software are expected to delay several key tests and put the program's production decision at risk. Third, the program experienced a Nunn-McCurdy unit-cost breach of the significant threshold and expects that integration and test delays could further increase costs. Finally, the JLENS program could be affected by alignment with the Army's Integrated Air and Missile Defense program. As part of the integrated strategy, the Army extended the system development phase for JLENS by 12 months.

Program Office Comments

In commenting on a draft of this assessment, the JLENS program provided technical comments, which were incorporated as appropriate.

Acquisition cycle time (months)	75	77	2.7

The JPALS program completed its critical design review in December 2010, but did not demonstrate that the design can perform as expected. As a result, the risk of design and software changes remains. JPALS functionality is software-based. According to program officials, the program has completed software qualification testing for four of five JPALS subsystems. Completion of testing of the ship processing software, which provides much of JPALS' functionality, has been delayed until March 2012 to incorporate an algorithm update. The program will begin integrated testing of a system prototype in January 2012 without this update. The program has delivered its first three engineering development models, with five more scheduled through 2012. Increment 1B, which integrates JPALS into sea-based aircraft, is planned to begin system development in 2012.

2237 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JPALS Program

Technology Maturity

JPALS Increment 1A began system development in July 2008 with its two critical technologies nearing maturity. Program officials expect both to be mature and demonstrated in a realistic environment by its May 2013 production decision. JPALS functionality is software-based, with over 850,000 lines of code expected in the final system as of August 2011—an increase of almost 57,000 lines of code since its December 2010 critical design review. According to program officials, all seven JPALS software blocks were completed in late August 2011 and the program has completed software qualification testing for four of five JPALS subsystems. Officials also noted that expected completion of testing for the ship processing software, which provides much of JPALS's functionality, has been delayed until March 2012 to allow the program time to integrate an updated version of an algorithm component. Any additional delays with this software testing could affect the JPALS test readiness review—a key program event—scheduled for April 2012.

Design Maturity

The JPALS design is currently stable, but it has not been demonstrated using a prototype to show that it will perform as expected. The risk of design and software changes will remain until the design shows it can meet requirements. The JPALS program held its critical design review in December 2010 and has released all of its expected design drawings to manufacturing. However, the program will not begin integrated testing of a system prototype until January 2012, and this testing will not include the ship processing software.

Production Maturity

The JPALS program plans to take steps to demonstrate the maturity of its manufacturing processes prior to beginning production. The program will demonstrate its manufacturing processes on a pilot production line and will demonstrate that the system will work as intended in a reliable manner by testing a fully configured production-representative prototype. The program accepted delivery of its first engineering development model in December 2010 and its second and third during 2011. Five additional models are scheduled for delivery through 2012, with initial models designated for land-based facilities testing and subsequent models for ship installation and testing. According to officials, the program's planned production decision was delayed from February 2013 to May 2013, primarily due to the availability of CVN 77 for ship-based testing.

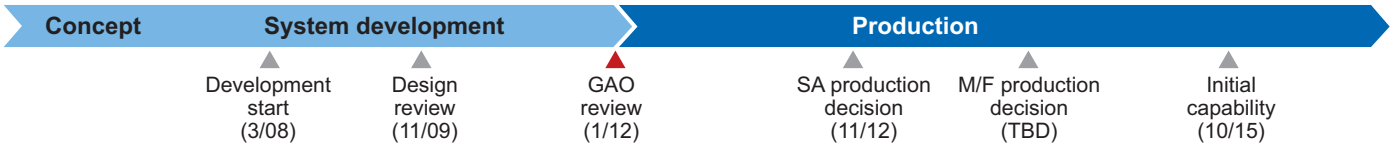
Other Program Issues

The JPALS program has not updated key acquisition documents for increment 1A and 1B. When increment 1A was approved to enter system development in 2008, the Under Secretary of Defense for Acquisition, Technology and Logistics stated that its test and evaluation master plan should be updated prior to its preliminary design review, which was held in December 2009. Program officials stated that they have revised the plan, and expect it to be finalized by the program's test readiness review. Increment 1B is scheduled to enter system development in 2012, but the program does not currently have an approved acquisition strategy.

The increment 1A program will integrate JPALS onto 20 existing ships; incorporating JPALS on new ships under construction is the responsibility of those respective programs.

Program Office Comments

In commenting on a draft of this assessment, the JPALS program office noted that increment 1A is currently preparing for entry into formal integrated testing. There have been no requirement changes, and the December 2010 critical design review concluded the program's technical baseline is stable, and performance, cost, and schedule risks are acceptable. All requests for action from the critical design review have been closed. The program completed early testing of the GPS subsystems on board LHD 1 in July 2011, mitigating several program risks prior to beginning formal testing. The program office received a production-representative ship system engineering development model in October 2011 and three functionally-representative avionics test kits in November 2011. To date, the program has continued to meet all cost, schedule, and performance thresholds. The program also provided technical comments, which were incorporated as appropriate.



2238 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Airborne and Maritime/Fixed Station Joint Tactical Radio System (AMF JTRS)

DOD's JTRS program is developing software-defined radios that will interoperate with existing radios and increase communications and networking capabilities. The AMF program will develop radios and associated equipment for integration into nearly 160 different types of aircraft, ships, and fixed stations. The program was developing two radios based on a common architecture: a 2-channel small airborne radio and 4-channel maritime/fixed station radio. DOD has suspended development work on the 4-channel radio.

Source: Lockheed Martin.

Program Essentials

Prime contractor: Lockheed Martin
Program office: San Diego, CA
Funding needed to complete:
R&D: $593.7 million
Procurement: $6,203.8 million
Total funding: $6,797.5 million
Procurement quantity: 26,878

Program Performance (fiscal year 2012 dollars in millions)

	As of 10/2008	Latest 08/2011	Percent change
Research and development cost	$1,945.0	$1,957.0	0.6
Procurement cost	$6,209.0	$6,203.8	-0.1
Total program cost	$8,154.1	$8,160.8	0.1
Program unit cost	$.301	$.301	0.1
Total quantities	27,102	27,102	0.0
Acquisition cycle time (months)	80	91	13.8

The program office reported quantities in terms of channels rather than radios.

The AMF JTRS program plans to enter production in November 2012, but it remains at risk for late and costly design changes until its critical technologies have been demonstrated in a realistic environment and other risks have been resolved. Growth in the processing requirements for one key AMF JTRS waveform—the wideband networking waveform—could require a hardware redesign. However, the program will not be able to determine whether one is needed until summer 2012 when the contractor demonstrates the waveform on an engineering development model. The AMF JTRS program has been directed by the Under Secretary of Defense for Acquisition, Technology and Logistics to restructure and delay further development of the maritime/fixed station radio because of unacceptable schedule delays and cost growth. Program officials are currently preparing a restructure plan.

2239 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

AMF JTRS Program

Technology Maturity

DOD approved the AMF JTRS program for entry into system development in March 2008 with all five of its critical technologies nearing maturity. According to the program, the maturity of these technologies has not changed. The program will not conduct a technology readiness assessment prior to the small airborne radio's production decision, as previously planned, because it is no longer required by DOD.

Design Maturity

The AMF JTRS design is currently stable; however, the program remains at risk for design changes until its critical technologies have been demonstrated in a realistic environment and other risks have been resolved. AMF JTRS' ability to meet its performance requirements is dependent on waveforms from the JTRS Network Enterprise Domain program. Growth in the processing requirements for one key AMF JTRS waveform—the wideband networking waveform—could result in design changes. According to program officials, the issue can be addressed by either making the waveform run more efficiently on the radio through software changes—the preferred solution—or by introducing a more-capable processor into the radio, which would require a hardware redesign. The program will not be able to determine whether the waveform's processing requirements can be reduced enough through efficiency gains until the contractor demonstrates the waveform on a small airborne engineering development model. There is a risk the delivery of the hardware for these models will be delayed. According to program officials, the Navy's Operational Test and Evaluation Force will conduct an operational assessment of the small airborne radio in preparation for its production decision, which is scheduled for November 2012.

According to the program office, AMF JTRS is on track to receive its security certification from the National Security Agency in early fiscal year 2013, but it will require an additional certification for its next software build, which includes functionality related to two key waveforms.

Production Maturity

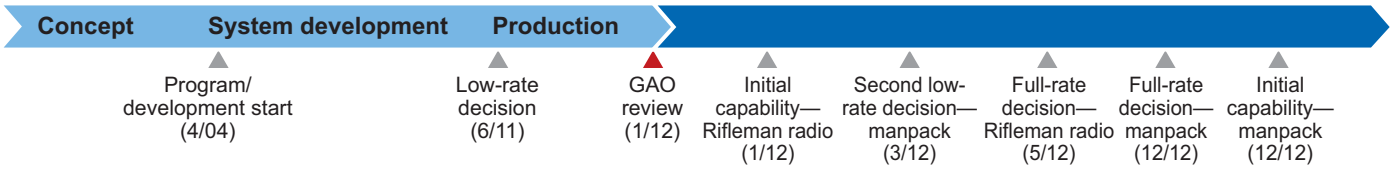
The AMF JTRS program plans to begin production in November 2012 with manufacturing processes that have been demonstrated, but are not in control. A joint government-contractor assessment team has conducted manufacturing readiness level assessments—which include assessing statistical process controls—at each manufacturing site. The program's projected level of manufacturing readiness indicates that not all statistical process controls will be in place at the start of production. Program officials reported that the prime contractor qualified a second manufacturing source.

Other Program Issues

In September 2011, the Under Secretary of Defense for Acquisition, Technology and Logistics directed that the AMF JTRS program be restructured because of unacceptable schedule delays and cost growth. The development of the maritime/fixed station radio was delayed and the Joint Requirements Oversight Council was requested to reconsider the requirement. According to the program, the military services have agreed that the small airborne radio can meet the maritime/fixed station requirements. In addition, the program was directed to restructure the AMF JTRS contract to reduce the government's cost risk for completing development of the small airborne radio and limit work to key waveforms.

Program Office Comments

In commenting on a draft of this assessment, AMF JTRS program officials provided technical comments, which were incorporated as appropriate.



2240 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Joint Tactical Radio System (JTRS) Handheld, Manpack, and Small Form Fit (HMS)

DOD's JTRS program is developing software-defined radios that will interoperate with existing radios and increase communications and networking capabilities. The JTRS HMS program is currently developing four radios: the Rifleman radio and small form fit radio D for unclassified use and the manpack radio and small form fit radio B for use in a classified domain. A subset of the manpack radios will be interoperable with the Mobile User Objective System (MUOS), a satellite communication system that will support radio terminals worldwide.

The JTRS HMS program entered production in June 2011 without demonstrating or assessing the maturity of all its critical technologies and with a lower level of manufacturing readiness than recommended by guidance. According to the program, its radio designs are stable; however, the program is still making software changes, and reliability and heat-related issues were identified in a June/July 2011 manpack test event. Manpack production was initially limited to 100 radios because of concerns about its maturity and performance in testing. A second production decision is expected for the manpack radio in March 2012. The estimated cost of the program has increased by $3.5 billion from what the program reported in 2010 as quantities increased to meet military service needs and to fulfill some of the requirements of the cancelled JTRS Ground Mobile Radios program.

2241 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JTRS HMS Program

Technology Maturity

The JTRS HMS Rifleman radio entered production in June 2011 without demonstrating the maturity of one of its critical technologies—the soldier radio waveform—in a realistic environment. The program office does not expect the assessment of the manpack radio's four critical technologies to be completed until April 2012.

Design Maturity

According to the JTRS HMS program, its radio designs are stable; however, the program is still demonstrating its critical technologies, making software changes, and addressing reliability and heat-related issues. The National Security Agency (NSA) has requested that the program modify some of its software code as part of its certification process. NSA certification, which is required due to JTRS's information-assurance needs, was expected to be complete for both radios by the end of 2011. Additionally, reliability and heat-related issues were identified in June/July 2011 manpack testing. Program officials attributed the problems to poor training of radio operators and do not anticipate that design changes will be needed to address them. The Under Secretary of Defense for Acquisition, Technology and Logistics has stated that the reliability and heat issues are significant risks for the manpack and limited its initial procurement to 100 radios. A second production decision is planned for March 2012 followed by operational testing in May 2012. The Rifleman radio also fell short of its reliability requirement in testing conducted in early 2011. However, according to program officials, the radio's performance was consistent with its reliability growth plan and they expect the radio will exceed its reliability requirements during operational testing, which is expected to be complete by February 2012.

Production Maturity

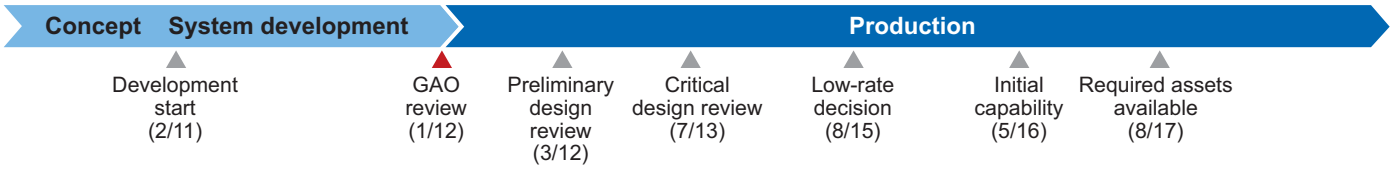
The JTRS manpack and Rifleman radios entered production in June 2011 at a lower level of maturity than DOD's manufacturing readiness level deskbook recommends. However, the program did demonstrate the production process for the Rifleman radio. According to the program office, the maturity of JTRS HMS manufacturing processes have been steadily increasing, so processes once deemed critical are now considered either key or standard processes.

Other Program Issues

The HMS program has experienced several changes to the number and types of radios it plans to buy since the start of development. Initially, the program planned to buy 328,674 radios at a cost of $10 billion. In 2010, the number of radios was 215,961 and the cost was $4.9 billion. In 2011, quantities and cost increased to 270,951 and $8.4 billion to accommodate requests for more radios from the military services and to fulfill some of the requirements of the cancelled JTRS Ground Mobile Radios program. At the same time, the program stopped developing two small form fit radios and the 2-channel handheld radio. Unit costs have increased for the remaining small form fit and manpack radios, and could continue to grow for future manpack variants. While the program office expects that competition will lower the procurement unit cost, program officials noted that delays in the MUOS program will likely have negative effects on the manpack radio's research and development cost and schedule. According to program officials, congressional funding reductions in fiscal year 2012 will also delay future releases of the manpack radio—including the MUOS-capable variant—and reduce planned radio purchases.

Program Office Comments

In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated as appropriate.



2242 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

KC-46 Tanker Modernization Program

The KC-46 tanker program is the first of three planned phases to replace the Air Force's fleet of KC-135 tankers, which have been its primary aerial refueling aircraft for more than 50 years. The initial purchase of 179 KC-46 aircraft is intended to replace roughly one-third of the KC-135 fleet's current capability. In addition to aerial refueling, the aircraft are being designed as a multirole platform supporting global attack, airlift, aircraft deployment, special operations, aeromedical evacuation, and combat search and rescue.

Program Essentials

Prime contractor: Boeing
Program office: Wright-Patterson AFB, OH
Funding needed to complete:
R&D: $6,055.9 million
Procurement: $33,502.6 million
Total funding: $43,283.6 million
Procurement quantity: 175

Program Performance (fiscal year 2012 dollars in millions)

	As of 08/2011	Latest 08/2011	Percent change
Research and development cost	$6,899.4	$6,899.4	0.0
Procurement cost	$33,502.6	$33,502.6	0.0
Total program cost	$44,127.2	$44,127.2	0.0
Program unit cost	$246.520	$246.520	0.0
Total quantities	179	179	0.0
Acquisition cycle time (months)	78	78	0.0

According to the Air Force, the development risk for the KC-46 is low to moderate because it will utilize a commercial derivative aircraft and maturing technologies; the integration of military software and hardware with the aircraft is the primary risk. The KC-46 tanker program entered system development in February 2011 with its three critical technologies nearing maturity. The program was granted a waiver to enter development without conducting a preliminary design review, but the program plans to hold this review in March 2012. The program also plans to have a stable design by its July 2013 critical design review. The KC-46 program is using a fixed-price incentive contract for development with options for production. The program office noted that stable requirements and funding will be key to mitigating potential cost growth.

2243 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

KC-46 Program

Technology Maturity

According to an independent technology readiness assessment, KC-46 entered system development with its three critical technologies nearing maturity. These technologies are a three-dimensional display to monitor and enable aerial refueling activities, and two types of software being developed to increase situational awareness and enable automatic aircraft rerouting to avoid potential threats. The integration of military hardware and software on the KC-46 aircraft's commercial derivative airframe has been identified as the primary technical risk for the program. Other technical risks include software development and the redesign of wing aerial refueling pods. In addition, the Federal Aviation Administration will have to certify both the Boeing 767-2C airframe and KC-46 tanker for air worthiness.

Design Maturity

The KC-46 tanker is a commercial derivative aircraft estimated to be 80 percent common with the Boeing 767 family of commercial platforms in terms of the airframe, and about 80 percent common with other Boeing commercial platforms in terms of system components. The KC-46 program did not require a technology development phase because it was assessed as having low to moderate development risk, and thus, did not hold a preliminary design review prior to beginning system development. The program received a waiver for this requirement and plans to hold this review in March 2012—about 13 months after development start. We have previously reported that holding a preliminary design review prior to development start can ensure requirements are well-defined and feasible. The program completed its system functional review—a predecessor to this review—in November 2011 resulting in no significant changes to program requirements. The program plans to demonstrate the system's design is stable and have 90 percent of KC-46 design drawings released by its projected July 2013 critical design review.

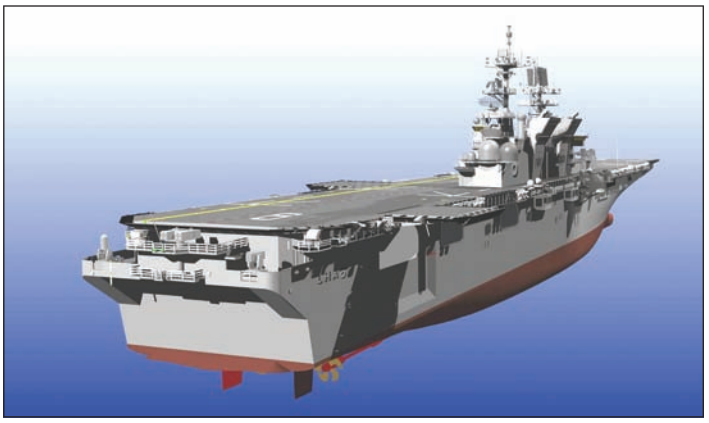
Production Maturity

The KC-46 program will not collect statistical process control data for critical manufacturing processes, but indicated that production maturity will be assessed using manufacturing readiness levels—a tool used to support assessments of manufacturing risks.

The significant concurrency between development, testing, and production activities poses a schedule risk for the KC-46 program. Following a successful initial production decision, the Air Force plans to exercise the first two production contract options. After the options are exercised, Boeing will be required to provide the Air Force with a total of 18 operationally ready aircraft 78 months after development contract award, which would be by August 2017. Further contract options are planned to continue through 2027. According to program officials, the government will hold Boeing accountable to the terms and conditions of the contract and seek consideration from Boeing if they do not perform to the contract requirements.

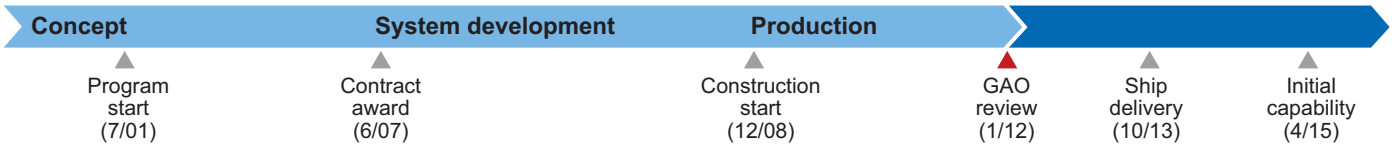
Other Program Issues

The Air Force awarded a $4.4 billion fixed-price incentive (firm target) contract to Boeing with a $4.9 billion ceiling price for four development aircraft with options for the remaining 175 planned production aircraft. The options establish firm-fixed pricing for low-rate initial production lots and not-to-exceed pricing for full-rate production lots. The program office cites stable requirements and funding as keys to mitigating potential cost growth.



Program Office Comments

In commenting on a draft of this assessment, DOD stated the program mitigated the greatest KC-46 risk to the taxpayer—cost growth and open ended financial liability—by negotiating the competitive fixed-price incentive development contract with firm-fixed and not-to-exceed pricing for production. In addition, the program is mitigating the development schedule risk by maintaining tight oversight of contract execution to ensure Boeing delivers on its contract commitments. DOD also stated the KC-46 program is being managed in an event-based manner and the approval to begin production is not driven by a contractually required date. DOD will mitigate the risk posed by concurrency by ensuring that adequate testing is completed prior to the production decision in addition to the contract provision requiring Boeing to incorporate fixes to issues found during testing into production aircraft at no additional cost. DOD and the Air Force also provided technical comments, which were incorporated as appropriate.



2244 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

LHA Replacement Amphibious Assault Ship

The Navy's LHA 6 class will replace the LHA 1 *Tarawa*-class amphibious assault ships. LHA 6 is a modified variant of the fielded LHD 8. It will feature enhanced aviation capabilities and is designed to support all afloat Marine Corps aviation assets in an expeditionary strike group. LHA 6 construction began in December 2008 and ship delivery is expected in October 2013. The LHA 6 class includes three ships. Navy officials expect to award the construction contract for LHA 7 by May 2012, with construction start planned for April 2013.

R&D: $97.3 million
Procurement: $5,627.9 million
Total funding: $5,726.2 million
Procurement quantity: 1

Program Performance (fiscal year 2012 dollars in millions)

	As of 01/2006	Latest 12/2010	Percent change
Research and development cost	$220.9	$350.9	58.8
Procurement cost	$2,959.2	$9,742.8	229.2
Total program cost	$3,180.2	$10,095.2	217.4
Program unit cost	$3,180.150	$3,365.053	5.8
Total quantities	1	3	200.0
Acquisition cycle time (months)	146	165	13.0

LHA 6 began construction in December 2008 with mature critical technologies, but a design that was only 65 percent complete. As of August 2011, the LHA 6 design was 98 percent complete and its construction was 52 percent complete. The shipbuilder is projecting an additional 6-month delay in the delivery of the ship, which is now expected in October 2013. According to the program office, this delay was caused by design quality issues—which have resulted in high levels of rework during construction—shortfalls in skilled-trade labor at the shipyard, problems implementing new shipbuilder business systems, and delays in receiving key materials. The LHA 6 program may also incur additional cost growth if postdelivery rework of the ship's deck is necessary to cope with the intense, hot downwash from the Joint Strike Fighter, which began shipboard testing in October 2011.

2245 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

LHA 6 America Class Program

Technology Maturity

All LHA critical technologies were mature when the program awarded its construction contract in June 2007. Although not considered critical technologies, the program has identified six key subsystems necessary to achieve LHA 6's full capabilities. Five of these subsystems are mature. The sixth, the Joint Precision Approach and Landing System, a Global Positioning System–based aircraft landing system, is still in development. LHA 6 can still meet its operational requirements without this system by using backup aviation control systems. The program office had also previously identified the machinery control system as a potential risk because the LHD 8 program, which is responsible for developing it, was experiencing delays in its development. However, according to program officials, the system's development, testing, and delivery are progressing on or ahead of LHA 6's schedule needs. Shipboard integration testing of the machinery control system is scheduled to begin in the second quarter of 2012.

Design and Production Maturity

The LHA 6 began construction in December 2008 with only 65 percent of its design complete, and subsequent design quality issues have caused a greater number of design changes than anticipated and high levels of rework during construction. The shipbuilder is also projecting an additional 6-month delay in the delivery of LHA 6, which is now expected in October 2013. As of August 2011, the LHA 6 design was 98 percent complete and its construction was 52 percent complete. The LHA 6's rework rate is more than twice that of the LHD 8—the last amphibious assault ship built—at the same stage of construction. According to program officials, LHA 6 has experienced a significant number of physical interference issues during construction that have required modifications, including ripping out of completed work, and caused work to stop at times. The program office attributes the high level of rework to insufficient quality checks of drawings prior to construction start. According to the program, shortfalls in skilled-trade labor at the shipyard, problems implementing new shipbuilder business systems, and delays in receiving key materials have also contributed to the projected delay in the delivery of the ship. Program officials said the manning situation at the shipyard has improved after the delivery of other Navy and Coast Guard ships.

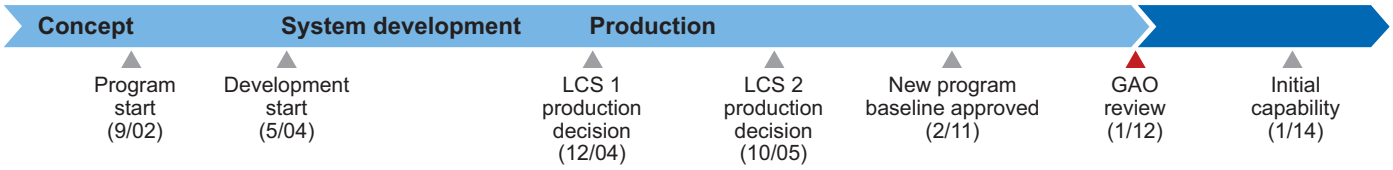
LHA 7 will have a design that is very similar to LHA 6. The ship will include a new firefighting system and updates to the radar and the command, control, communications, computers, and intelligence systems. Design changes to LHA 8 are projected to be more significant because the Navy is expected to include a well deck on the ship, which would accommodate landing and attack craft, but negatively affect aviation capabilities such as fuel storage space.

Other Program Issues

LHA 6 may experience further cost growth due to issues related to the deployment of the Joint Strike Fighter. Specifically, postdelivery rework of the ship's deck may be necessary to cope with the heat from the aircraft's exhaust and downwash, which could warp the deck or damage deck equipment. In October 2011, the Navy began at-sea testing on the USS *Wasp* to determine how LHA 6 and other JSF-capable ships may need to modify their flight decks.

Program Office Comments

In commenting on a draft of this assessment, the Navy stated that LHA 6, awarded under a fixed-price contract, was 60 percent complete as of February 2012 and on track to be delivered in fiscal year 2014. The Navy also stated that LHA 6 experienced a higher rework rate than LHD 8 at the same stage of construction for two main reasons. First, the shipbuilder performed more work at an earlier phase by increasing the amount of preoutfitting in the ship compared to LHD 8. More rework is being experienced earlier in construction, where it is less expensive to perform. LHD 8 experienced the majority of rework at later construction phases. Second, the significant physical interference issues during construction have required modification. Shipbuilder quality performance is improving in electrical cable installation, hull joint fit-up, and weld quality, and several construction milestones, such as stern release, have been achieved ahead of schedule. Test procedure development is also ahead of schedule. The Navy also provided technical comments, which were incorporated as appropriate.



2246 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Littoral Combat Ship (LCS)

The Navy's LCS is designed to perform mine countermeasures, antisubmarine warfare, and surface warfare missions. It consists of the ship itself, or seaframe, and the mission package it deploys. The Navy bought the first four seaframes in two unique designs. In December 2010, the Navy changed its planned strategy of choosing one design for future ships and instead, subsequently awarded a contract for a block buy of up to 10 ships to both contractors. We assessed both seaframe designs.

Total quantities	4	55	1,275.0
Acquisition cycle time (months)	41	116	182.9

Cost data are for the seaframe only. The 2004 estimate corresponds with program initiation. It was pre–milestone B and did not reflect the full 55-ship program. Research and development funding includes detail design and construction of two ships.

The LCS program is entering a period of steady production and has demonstrated the maturity of most of its critical technologies; however, it continues to make design and production process changes. The Navy started construction of LCS 1 and 2 without a stable design and has had to incorporate design changes on follow-on seaframes. The Navy believes it has identified measures to address cracking on the LCS 1's superstructure and hull and corrosion issues on LCS 2 that can be achieved within the program's budget. DOD's Office of the Director, Cost Assessment and Program Evaluation, has stated that the program may be at risk for cost growth because its approved cost estimate reflects competitive pricing from recent contracts that may not materialize in the future.

2247 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

LCS Program

Technology Maturity

Sixteen of the 19 critical technologies for both LCS designs are mature and have been demonstrated in a realistic environment. Three technologies—LCS 1's overhead launch and retrieval system and LCS 2's aluminum structure and trimaran hull—are nearing maturity. The LCS 1 overhead launch and retrieval system, which is essential to antisubmarine warfare and mine countermeasures missions, has moved weight equivalent to a mission system, but has not yet demonstrated its maturity by loading and offloading an actual mission module vehicle. Program officials stated that a test of the Remote Multi-Mission Vehicle with the launch and recovery system has not been scheduled and will depend on the availability of LCS 1 and the vehicle. Developmental testing for the vehicle is scheduled for 2013. In addition, program officials believe that LCS 2's aluminum structure and trimaran hull are mature because the ship is operational. However, an April 2010 independent technology readiness assessment did not reach the same conclusion about the aluminum structure, in part because of the inability to assure a 20 year service life.

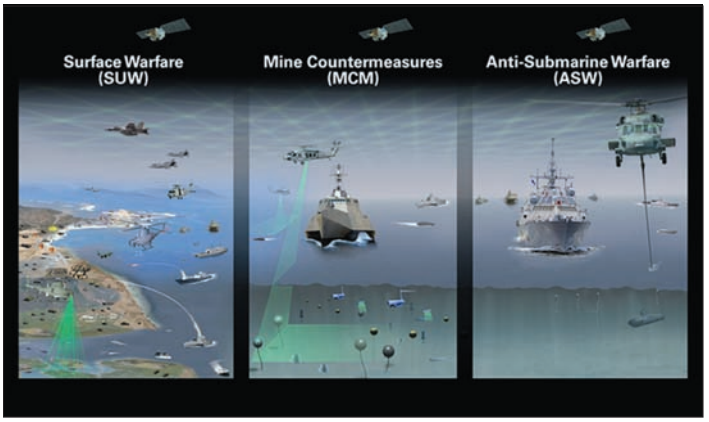
Design and Production Maturity

The Navy started construction of LCS 1 and 2 without a stable design and has had to incorporate design and production changes into follow-on seaframes. When the LCS 1 and 2 construction contracts were awarded, the basic and functional design of each seaframe were respectively only 20 percent and 15 percent complete. Construction began 1 to 2 months following these contract awards. This concurrent design-build strategy ultimately led to increases in construction costs.

LCS 1 has been in operation for about 3 years and the Navy has discovered cracks in the superstructure and hull. The program office indicated that the cracks occurred either in high stress areas on the ship or due to workmanship issues, such as welding deficiencies. Program officials stated that all cracks have been fixed and design changes and improved production processes, such as improving accessibility in welding areas, are being developed. The design changes, which decrease the stress on parts of the ship, will also be made on LCS 3, which is almost complete, as well as future seaframes. The Navy also reported corrosion on LCS 2, which has been in operation for over a year, due to insufficient insulation between the aluminum hull and the steel water jet. The Navy plans to install a system to mitigate the deterioration of metals on LCS 2 and future seaframes. The Navy believes these measures are sufficient to address the cracking and corrosion issues and can be done within the program's budget.

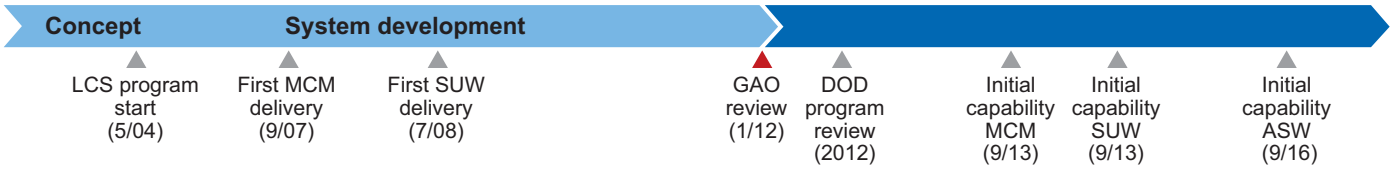
Other Program Issues

The LCS's approved program baseline is based on a cost estimate that is lower than an independent cost estimate from the Office of the Director, Cost Assessment and Program Evaluation. The Under Secretary of Defense for Acquisition, Technology and Logistics stated that the approved cost estimate is reasonable as it reflects the expectation that recent competitive pricing will continue for future contracts. The Director, Cost Assessment and Program Evaluation, expressed concern that this approach puts the program at risk for future cost growth if these savings do not materialize.



Program Office Comments

In commenting on a draft of this assessment, the Navy stated that it has retired the increased construction costs associated with the concurrent design/build period. The Navy noted that due to the complex nature of ship design and construction, lead ships generally have design changes that are incorporated into follow-on ships as a result of extensive testing and ship underway lessons learned. That is common practice in ships, even with a stable baseline, as evidenced by changes incorporated in the DDG 51 Class. LCS 3 and 4 have experienced minimal design changes and reflect learning, with both shipbuilders investing in their shipyards. LCS 3 is 99 percent complete and will deliver in June 2012. LCS 4 was about 80 percent complete at launch and was christened in January 2012. LCS 5 completed a detail design review and a production readiness review and its fabrication began in August 2011. LCS 6 followed suit and started fabrication in August 2011. Technical comments provided by the Navy were incorporated as appropriate.



2248 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Littoral Combat Ship–Mission Modules

The Navy's Littoral Combat Ship (LCS) will perform mine countermeasures (MCM), surface warfare (SUW), and antisubmarine warfare (ASW) missions using mission modules. Modules include weapons and sensors operating from MH-60 helicopters and unmanned vehicles, which will be launched and recovered from both LCS seaframes. The mission modules program is separate from the LCS seaframe for management and reporting purposes. The Navy has defined increments of MCM, SUW, and ASW capability that it plans to deliver incrementally, over time.

Program Essentials

Prime contractor: Multiple
Program office: Washington, DC
Funding FY12 to FY16:
R&D: $657.4 million
Procurement: $969.3 million
Total funding: $1,626.7 million
Procurement quantity: 18

Program Performance (fiscal year 2012 dollars in millions)

	As of 08/2007	Latest 09/2011	Percent change
Research and development cost	$491.8	$1,652.4	236.0
Procurement cost	$3,259.2	$1,228.0	-62.3
Total program cost	$3,751.0	$2,880.4	-23.2
Program unit cost	NA	NA	NA
Total quantities	64	65	1.6
Acquisition cycle time (months)	NA	NA	NA

Costs are from program start through fiscal year 2016. The program's cost estimate has been updated by the Navy and a baseline will be set after DOD's upcoming review of the program.

The MCM, SUW, and ASW mission modules, at full capability, require a total of 24 critical technologies, including sensors, vehicles, and weapons—none of which, at full capability, have been tested on board LCS in a realistic environment. In addition, some of the sensors, vehicles, and weapons that the Navy previously assessed as mature are being replaced because of poor performance or increasing costs. The Navy is continuing developmental testing but has yet to begin operational testing. The Navy has accepted delivery of two partially capable MCM and SUW mission modules, each, for a total of four. In 2012, the Navy plans to accept delivery of a total of three MCM and SUW mission modules and also plans to procure two more partially capable modules. The Navy plans to procure 24, and deliver 9, LCS seaframes by 2016, before delivering a single fully capable mission module.

2249 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

LCS Modules Program

Mine Countermeasures (MCM)

The Navy has accepted delivery of two partially capable MCM mission modules and, in 2012, expects to accept delivery of a module and procure another module. The Navy plans to begin operational testing onboard LCS in 2012, but the contents of the MCM module are still changing to address cost and capability concerns. For example, the remote minehunting system (RMS), comprised of an underwater vehicle and sonar, experienced a Nunn-McCurdy unit-cost breach in 2009. Further, the Navy has found performance issues, in part because the equipment required to launch and recover the underwater vehicle is not reliable and sonar performance does not currently meet threshold requirements. Since the Navy already purchased 10 underwater vehicles and determined there is no better alternative, RMS will remain in the module. The Navy is currently executing a plan to improve its reliability and then plans to begin producing the upgraded RMS in 2015. The rapid airborne mine clearance system was initially part of the MCM module, but was removed because of performance problems when destroying below-surface mines. The Navy plans to replace it by 2017. The Navy has also removed the unmanned surface vehicle (USV) and unmanned influence sweep system from its upcoming mission module. The USV design does not meet requirements, requiring a 6-year effort to improve the system's capabilities. The Navy has also deferred delivery of two other MCM systems.

Surface Warfare (SUW)

The Navy has accepted delivery of two partial SUW modules, including two 30 millimeter guns and a prototype of an 11-meter small boat. In 2012, the Navy plans to accept delivery of two and procure one more partial module. The Navy has replaced the cancelled Non-Line-of-Sight Launch System—which had a proposed range of 21 nautical miles—with the Griffin missile, which according to officials, will initially have a range of 3 miles. The Navy will not incorporate a surface-to-surface missile that can meet the module's requirements until after 2017 following a full and open competition.

Antisubmarine Warfare (ASW)

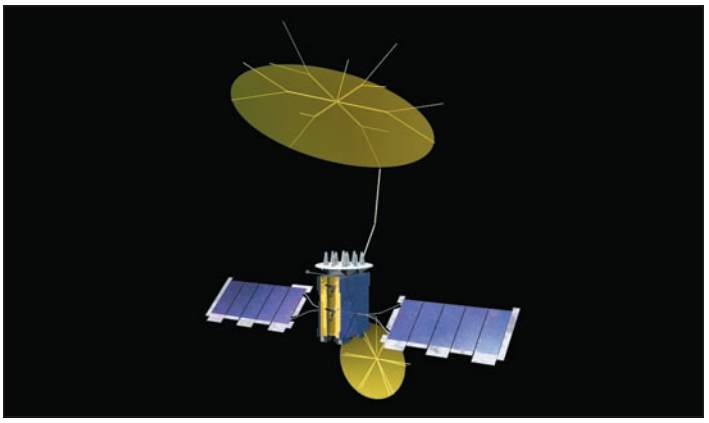
In 2008, the Navy took delivery of one partially capable ASW module at a cost of over $200 million, but subsequently cancelled plans to continue procuring the module and is redesigning it. According to program officials, the new design includes a variable-depth sonar and towed array, unmanned aerial vehicle, helicopter, and torpedo countermeasure. These ASW technologies are in use by another navy, but they have not been adapted for use with LCS. In 2012, the Navy will begin engineering analysis of the new ASW module, followed by development start in 2013 and initial delivery in fiscal year 2016.

Other Program Issues

The Navy plans to purchase 24, and deliver 9, LCS seaframes by 2016; however, it will not have a single fully capable mission module at that time. As of September 2011, the program planned to conduct a key DOD review in January 2012; however, this review, which includes a program cost estimate and technology maturity assessment, has been delayed to an unspecified date in 2012.

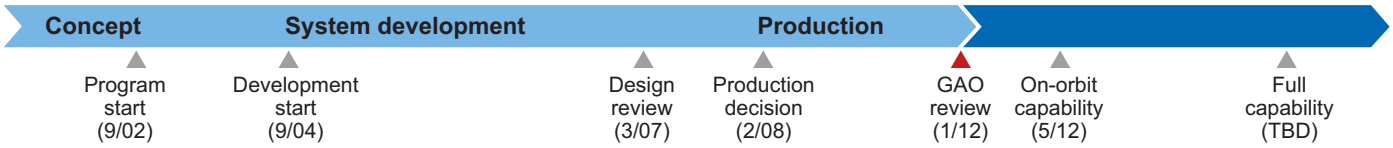
Program Office Comments

In commenting on a draft of the assessment, the program office did not concur with our assessment of the LCS Mission Modules; specifically with regard to the state of development and maturity of the mission modules. The program believes that recent testing has been very successful. For example, the MCM module has recently completed developmental and end-to-end testing to neutralize mines. The SUW module supported deployment of LCS 1 on missions that resulted in the capture of cocaine. From inception, the program has remained stable, fielding systems as they achieve the required level of maturity. The few systems experiencing issues are being replaced with alternative systems or are targets of increased focus and attention. The program also provided technical comments, which were incorporated as appropriate.



GAO Response

Major elements of each of the three mission modules have yet to be demonstrated and there are unknowns about their cost and performance. Until the program demonstrates these capabilities in a realistic environment, the program will be at increased risk of cost growth, schedule delays, and performance shortfalls.



2250 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Mobile User Objective System (MUOS)

The Navy's MUOS, a satellite communication system, is expected to provide a worldwide, multiservice population of mobile and fixed-site terminal users with increased narrowband communications capacity and improved availability for small terminal users. MUOS will replace the Ultra High Frequency (UHF) Follow-On (UFO) satellite system currently in operation and provide interoperability with legacy terminals. MUOS consists of a network of satellites and an integrated ground network. We assessed both the space and ground segments.

Program Essentials

Prime contractor: Lockheed Martin Space Systems
Program office: San Diego, CA
Funding needed to complete:
R&D: $470.1 million
Procurement: $1,125.1 million
Total funding: $1,595.2 million
Procurement quantity: 1

Program Performance (fiscal year 2012 dollars in millions)

	As of 09/2004	Latest 08/2011	Percent change
Research and development cost	$3,647.7	$4,218.3	15.6
Procurement cost	$3,035.0	$2,694.3	-11.2
Total program cost	$6,721.3	$6,978.2	3.8
Program unit cost	$1,120.222	$1,163.035	3.8
Total quantities	6	6	0.0
Acquisition cycle time (months)	90	116	28.9

The latest cost data do not reflect the current cost of the program. A new acquisition program baseline has not yet been approved.

The MUOS program's critical technologies are mature, its design is stable, and its manufacturing process maturity is increasing. The first satellite has been delivered and is expected to begin on-orbit operations in May 2012—26 months later than planned at development start. The delivery of MUOS capabilities remains time-critical due to the past operational failures of two UFO satellites. If the first satellite is launched as scheduled, the risk of UHF communications capabilities falling below required levels will be substantially reduced. However, users will not be able to utilize many MUOS capabilities until two MUOS satellites are in orbit and because of delays in the development and testing of a new waveform and fielding of user terminals. MUOS user terminal procurement and fielding are managed by separate programs.

2251 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MUOS Program

Technology, Design, and Production Maturity

The MUOS program's critical technologies are mature, its design is stable, and its manufacturing process maturity is increasing. The first satellite has been delivered and four other satellites are being built. Despite some delays, system-level thermal vacuum testing—used to demonstrate the performance of the payload and spacecraft in a simulated space environment—has been completed for the first satellite. In addition, the design flaws that we reported on last year—including unwanted signal interference caused by UHF reflectors and the hinges that connect solar panels and booms in the solar array wing assembly—have been resolved. These components have been reworked and tested; final signal interference testing results were completed in November 2011. According to the program office, the production maturity of the first MUOS satellite is high. The program has experienced quality problems in the past that resulted in cost increases and schedule delays. However, the number of manufacturing defects on the space segment has decreased slightly over time as the maturity of the manufacturing process has increased. We could not assess whether MUOS critical manufacturing processes were in control because the program does not collect statistical process control data.

Other Program Issues

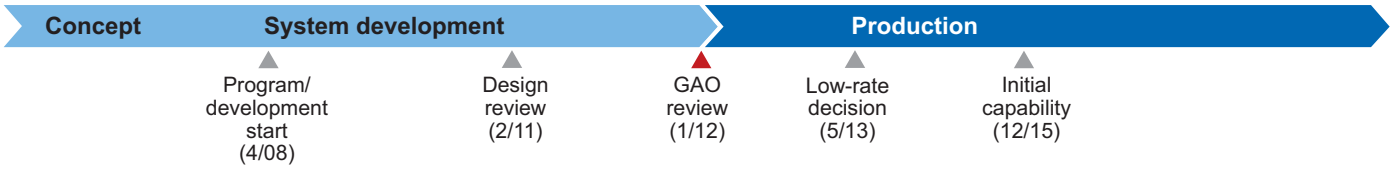
The first MUOS satellite has been delivered for a planned February 2012 launch. Current UHF communication capabilities are predicted to provide the required availability level until the first MUOS satellite begins on-orbit operations—planned for May 2012. The MUOS program has taken actions to address a potential capability gap caused by earlier, unexpected UFO satellite failures by activating dual digital receiver unit operations on a UFO satellite, leasing commercial UHF satellite services, initiating international partner agreements to share UHF satellite capacity, and planning to enhance digital receiver unit operations on the second through fifth MUOS satellites.

According to the program office, its top challenge is synchronizing deliveries of the MUOS space and ground segments with compatible Joint Tactical Radio System (JTRS) terminals. Launching the first MUOS satellite is important to sustain current UHF communications capability, but there is a risk that MUOS capabilities will be significantly underutilized because of delays in the JTRS program's development and delivery of the new MUOS waveform and radio terminals. Over 90 percent of the MUOS's planned capability is enabled by the new waveform and JTRS terminals, including increases in the amount of data that can be transmitted and the ability to transmit both voice and data. Operational testing of the JTRS terminals has been delayed to February 2014. An independent review team assessed potential options for completing development of the MUOS waveform and the plan forward is being finalized.

In 2009, a Navy-initiated review of the MUOS program found that while it was technically sound, its schedule was optimistic and its budget was inadequate. As a result, the program developed new cost and schedule baselines. The new baseline has been under revision since December 2009, but has not yet been approved.

Program Office Comments

In commenting on a draft of this assessment, the Navy provided technical comments, which were incorporated as appropriate.



2252 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MQ-4C Broad Area Maritime Surveillance (BAMS) Unmanned Aircraft System (UAS)

The Navy's MQ-4C BAMS UAS is intended to provide a persistent maritime intelligence, surveillance, and reconnaissance (ISR) capability even when no other naval forces are present. BAMS UAS will operate from five land-based sites worldwide. It will be part of a family of maritime patrol and reconnaissance systems that recapitalizes the Navy's airborne ISR assets. Follow-on increments of the program will add a signals intelligence capability and upgrade the system's communication relay. We assessed Increment 1.

The BAMS UAS program's critical technologies are mature and its design is stable; however, the program does not plan to demonstrate that the design performs as expected until April 2012—more than a year after the critical design review. According to program officials, the second BAMS UAS system development aircraft, which will begin testing in 2012, will be the first aircraft with a full sensor suite and the air-to-air radar subsystem. In November 2011, the BAMS UAS program received approval to build three systems and ground stations, in part to demonstrate its manufacturing processes prior to its planned May 2013 production decision. According to program officials, the BAMS air vehicle is based on the Air Force's RQ-4B Global Hawk with some structural changes to the airframe, but none of these require significant changes to manufacturing processes.

2253 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

BAMS UAS Program

Technology Maturity

The BAMS UAS program's critical technologies are mature. DOD and the Navy certified that all BAMS UAS technologies had been demonstrated in a relevant environment before the start of system development, and an April 2011 technology readiness assessment concluded that its one critical technology—a hydrocarbon sensor—was mature. This sensor is identical to one that has been developed for the Navy's P-8A program. The maturity of the BAMS air-to-air radar subsystem, which will enable its sense and avoid capabilities, has not been assessed.

Design Maturity

The BAMS UAS design is stable; however, the program does not plan to demonstrate the design performs as expected by testing an integrated prototype until April 2012—more than a year after the critical design review. According to the program office, 97 percent of the air vehicle's expected design drawings are releasable to manufacturing and all subsystem critical design reviews have been completed. The second BAMS UAS system development aircraft, which will begin testing in 2012, will be the first aircraft with a full sensor suite and the air-to-air radar subsystem.

The BAMS UAS program poses a significant software development challenge, utilizing nearly 8 million lines of code, of which more than 20 percent will be newly developed for the program. Program officials cited software development as a primary risk for one subsystem, the air-to-air radar, but noted that they still expect it to be ready for the program's planned operational assessment in 2013.

Production Maturity

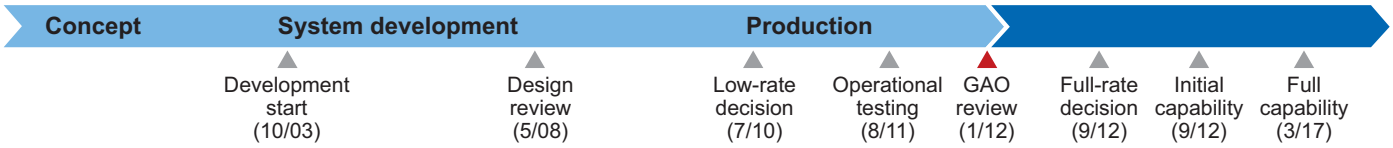
In November 2011, the BAMS UAS program received approval to build three air vehicles and associated ground stations, in part to demonstrate its manufacturing processes prior to production. According to program officials, the program also plans to assess manufacturing maturity and risks, using manufacturing readiness levels, before its planned production decision in May 2013. The BAMS aircraft is based on the Air Force's Global Hawk RQ-4B, which is in production, and uses sensor components and entire subsystems from other platforms. There are some structural changes to the airframe, but none of these require significant changes to manufacturing processes.

Other Program Issues

The BAMS UAS program has not reported any negative effects as a result of past challenges in the Global Hawk program; however, we did not assess the effect of the proposed cancellation of the Global Hawk Block 30 program. According to the BAMS UAS program office, the performance and reliability issues experienced by the Global Hawk during operational testing have already been addressed for the BAMS UAS. In addition, the BAMS UAS program has reported to the Navy on the potential cost effects of reduced Global Hawk procurements, which occurred after that program experienced a Nunn-McCurdy unit-cost breach of the critical threshold in 2011. Despite changes to the Global Hawk program, the BAMS UAS program is continuing to investigate potential areas of commonality with it, including a common ground control station architecture, a consolidated maintenance hub, and colocated basing for both UASs abroad. The Navy acquired three additional Global Hawk Block 10 aircraft divested by the Air Force. These aircraft will be used to provide additional parts support to maintain the BAMS demonstrator capability supporting overseas operations until BAMS UAS reaches initial operating capability scheduled for 2015.

Program Office Comments

In commenting on a draft of this assessment, the Navy stated that, while the software development, system integration, and integrated test efforts pose challenges for the BAMS UAS program in the coming years, proactive risk mitigation and detailed cost and schedule management to this point have provided the basis for successful completion of upcoming program milestones. According to officials, the program benefits from strong support within the Department of the Navy, fills a tremendous need for intelligence, surveillance, and reconnaissance capability, and is on track for initial operational capability in fiscal year 2016. Additionally, the Navy provided technical comments, which were incorporated as appropriate.



2254 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Navy Multiband Terminal (NMT)

The Navy's NMT is a next-generation maritime military satellite communications terminal that will be installed in existing ships, submarines, and shore sites. NMT is designed to work with the Air Force's Advanced Extremely High Frequency (AEHF) satellite system to provide protected and survivable satellite communications to naval forces. Its multiband capabilities will also enable communications over existing military satellite communication systems, such as Milstar, Wideband Global SATCOM, and the Defense Satellite Communications System.

The NMT program entered production in July 2010 with mature critical technologies, a stable design, and production processes that had been demonstrated, but were not in control. The program will complete a manufacturing readiness assessment to demonstrate its maturity prior to its full-rate production decision, targeted for September 2012. According to the program office, the number of design changes in fiscal year 2011 was greater than anticipated as a result of test failures. The NMT program's software lines of code also increased after the Navy added a capability to support communication with the Enhanced Polar System. NMT completed initial operational test and evaluation in August 2011, and DOD's independent test organization found that the system was operationally effective, but not operationally suitable because it did not meet certain reliability requirements during the test.

2255 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

NMT Program

Technology Maturity

The NMT program's two critical technologies—a multiband antenna feed and monolithic microwave integrated circuit power amplifiers for Q-band and Ka-band communication frequencies—are mature.

Design Maturity

The NMT's design is stable and the program has released all of its expected design drawings. According to the program office, the number of design changes in fiscal year 2011 was greater than anticipated because two subassemblies were redesigned to address failures in testing. The overall effect of these changes on the program was minor. The NMT program's software lines of code have increased since the start of production because the Navy requested that the program add a capability to support communication with the Enhanced Polar System. Overall, software integration testing is over 95 percent complete with over 98 percent of the defects resolved.

Production Maturity

The NMT program office began production in July 2010 with processes that had been demonstrated on a pilot line, but were not in control. The program estimates that three of its five processes are now in statistical control. According to the program office, a production readiness review will be performed prior to the NMT's full-rate production decision, which is expected to occur in September 2012. The program will also complete a manufacturing readiness assessment to demonstrate that it is mature enough for full-rate production.

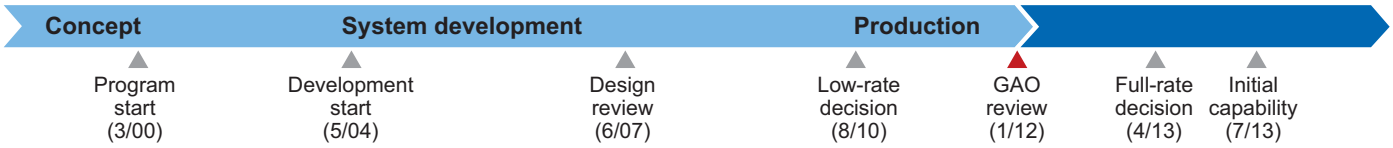
Other Program Issues

NMT completed initial operational test and evaluation in August 2011. The Navy's and DOD's independent test organizations found that NMT was operationally effective, but not operationally suitable because it did not meet certain reliability requirements. The program has identified corrective actions to address the shortfalls. As a result of the test findings, program officials stated they will extend low-rate production and delay the full-rate production decision from December 2011 to September 2012.

NMT is dependent on AEHF satellites to test its full range of capabilities. The first AEHF satellite was launched in August 2010; however, a satellite propulsion system anomaly delayed the satellite from reaching its planned orbit until October 2011. AEHF delays directly affect the ability of the NMT program to test its extended-data-rate communications capability. According to NMT program officials, risk-reduction testing was conducted using an advanced AEHF simulator; on-orbit testing was completed with Milstar satellites; and ground testing of low-, medium-, and extended-data-rate capabilities was done with the second AEHF satellite. The second AEHF satellite is expected to launch in April 2012, and follow-on operational testing, which will include on-orbit AEHF satellites, will begin in early fiscal year 2014. In the interim, program officials stated that fielded NMT systems can provide value by accessing existing satellite communication systems such as the Defense Satellite Communications System, Milstar, Wideband Global SATCOM, Interim Polar, and UFO satellite constellations. The realization of the NMT's full operational capability has been delayed 2 years to 2017 to better align with the warfighter's needs.

Program Office Comments

In commenting on a draft of this assessment, the Navy stated that the NMT program is in low-rate initial production, moving toward a full-rate production decision. The program will demonstrate the fixes for the shortfalls identified in initial operational test and evaluation through verification testing, including on operational platforms. The Navy further stated that NMT is committed to providing deployed naval commanders with assured access to secure, protected command and control and communication capabilities to support the exchange of warfighter-critical information. NMT will support the Navy's net-centric FORCEnet architecture and act as an enabler for transforming operational capability available to the warfighter. The Navy also provided technical comments, which were incorporated as appropriate.



2256 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

P-8A Poseidon

The Navy's P-8A Poseidon is a Boeing commercial derivative aircraft that will replace the P-3C Orion. Its primary roles are antisubmarine warfare; antisurface warfare; and intelligence, surveillance, and reconnaissance. The P-8A is a part of a family of systems that share the integrated maritime patrol mission and support the Navy's maritime warfighting capability. The program plans to field capabilities in three increments. We assessed increment one and made observations on increment two.

The P-8A entered production in August 2010 with mature technologies, a stable design, and proven production processes. The program is conducting its remaining development activities concurrently with production, which puts the program at increased risk of experiencing late and costly design changes. The number of design drawings has increased slightly in the last year to address deficiencies discovered during testing. The manufacturing processes for the P-8A airframe are proven. The processes for key aircraft subsystems have also been assessed as generally mature, although the program has experienced quality issues with some of them. The Navy has identified the execution of testing as a risk, which program officials stated has delayed the start of initial operational test and evaluation from April to June 2012. The program is taking steps to reduce this schedule pressure.

P-8A Program

Technology Maturity

The P-8A entered production in August 2010 with mature technologies. The current critical technology, the hydrocarbon sensor, has been tested in ground-based applications and program officials indicated that flight testing will occur in fiscal year 2012. The program also noted that it has begun flight testing the ESM digital receiver and the sonobuoy launcher, two technologies that were previously identified as being critical but are no longer designated as such based on their use in other platforms.

The P-8A program has been authorized to incorporate a set of capabilities initially planned as a separate increment into the baseline program primarily because these improvements will entail the integration of mature technologies into the aircraft.

Design Maturity

The program entered production with a stable design; however, system development efforts are continuing concurrently with production, putting the program at increased risk of late and costly design changes. The number of design drawings has increased slightly since August 2010 as a result of deficiencies discovered during testing. Program officials stated that they are still determining how to incorporate changes identified during developmental testing into the initial production aircraft, noting that the strategy will depend upon the availability of funding.

Production Maturity

The manufacturing processes for the P-8A have been proven. The program demonstrated its airframe manufacturing processes on a commercial line prior to entering into production. The manufacturing readiness levels associated with the P-8A's main subsystems indicate their processes are also generally mature, although the program has encountered quality issues with the on-board inert gas generator system and auxiliary fuel tanks, which are currently being addressed by the prime contractor. Delivery of the first production aircraft is scheduled for February 2012.

Other Program Issues

The P-8A airframe has been designated a commercial item. As a result, the contractor is not required to submit cost or pricing data to the government. Program officials stated that this designation has not affected recent contract negotiations, and the program negotiated a 10 percent lower unit cost on its second production contract. The commercial item designation has also generated concerns in the past from the Defense Contract Management Agency (DCMA) about the government's access to production facilities and its ability to conduct surveillance. However, DCMA has started reporting on aircraft quality at the Boeing commercial facility in Washington responsible for the wing, tail, aircraft assembly, and engine installation.

The operational assessment of the P-8A conducted prior to production start found that the system demonstrated the expected level of maturity, but it also identified a number of shortfalls, including sonobuoy and weapons deployment. The Director, Operational Test and Evaluation, noted that some of these shortfalls degraded mission performance, and, if not addressed, may pose a risk to the program successfully completing initial operational test and evaluation. The Navy and DCMA have also identified the execution of testing as a risk, which program officials stated has delayed the start of initial operational test and evaluation from April to June 2012. The program is focused on maintaining flight test execution rates while it pursues opportunities to reduce this schedule pressure.

Program Office Comments

In commenting on a draft of this assessment, the Navy stated that the program continues to execute its test plan in preparation for the start of initial operational test and evaluation. Testing has been an identified risk as a result of inefficiencies in execution; however, extensive corrective actions have been implemented to manage this risk. Program officials said that although the corrective actions have improved the efficiency of test execution, the program has adjusted the start of initial operational test and evaluation from April 2012 to June 2012, which is still within the program's approved baseline. In addition, the program is working to capture, correct, and test deficiencies identified in testing and manage this risk. The Navy also provided technical comments, which were incorporated as appropriate.

Reaper Unmanned Aircraft System (UAS)

The Air Force's MQ-9 Reaper is a multirole, medium-to-high-altitude endurance unmanned aircraft system capable of flying at higher speeds and higher altitudes than its predecessor, the MQ-1 Predator A. The Reaper is designed to provide a ground-attack capability to find, fix, track, target, engage, and assess small ground mobile or fixed targets. Each system consists of four aircraft, a ground control station, and a satellite communications suite. We assessed the increment I block 5 configuration and made observations on block 1.

Source: U.S. Air Force.

Program Essentials

Prime contractor: General Atomics Aeronautical Systems, Inc.
Program office: Wright-Patterson AFB, OH
Funding needed to complete:
R&D: $420.5 million
Procurement: $7,962.6 million
Total funding: $8,473.5 million
Procurement quantity: 240

Program Performance (fiscal year 2012 dollars in millions)

	As of 02/2008	Latest 08/2011	Percent change
Research and development cost	$420.1	$920.3	119.1
Procurement cost	$2,111.5	$10,848.3	413.8
Total program cost	$2,637.1	$11,918.7	352.0
Program unit cost	$25.115	$29.871	18.9
Total quantities	105	399	280.0
Acquisition cycle time (months)	79	94	19.0

The block 1 Reaper is in production, but the block 5 production decision was delayed 2 years to July 2013 to allow time for the program to fully integrate and test upgrades, such as system power increases, modernized crew stations, and improvements to the primary data link. Although the Reaper's critical technologies are mature and all design drawings have been released, the block 5 is still at risk for design changes until its upgrades are integrated and tested. According to program officials, operational testing for block 5 was also delayed 1 year to November 2013. This testing will include an evaluation of the block 1's hunter and net-ready capabilities, which were not included in its initial operational testing in 2008. The user is reevaluating its requirements and strategy for managing future Reaper upgrades; the increment II program was to begin in fiscal year 2012.

2259 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Reaper Program

Technology Maturity

The Reaper's block 1 and block 5 critical technologies are considered mature. An Air Force technology readiness assessment conducted in 2010 identified two critical technologies for the block 5 configuration—a high-capacity starter/generator and modified engine—and assessed them as mature. In addition to these critical technologies, there are other key enhancements for block 5 that are expected to improve the capability of the system, including upgrades to the radar, data link, sensor, landing gear, and ground control stations. These upgrades must still be successfully integrated and tested on the MQ-9 system. The production decision for the block 5 has been delayed by 2 years to July 2013 because of concerns about software delays and the amount of developmental and integration testing remaining.

Design Maturity

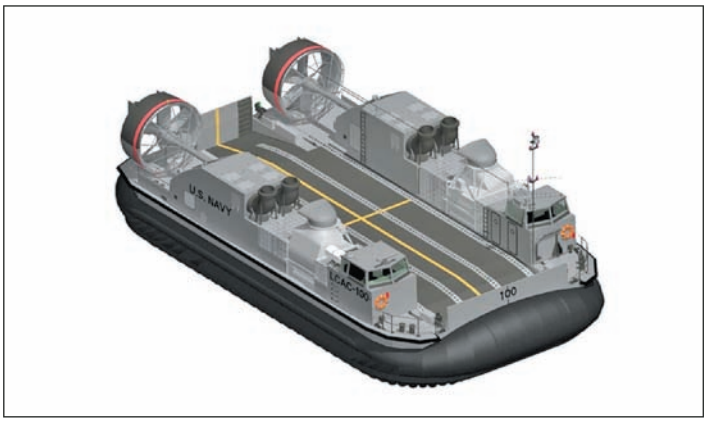
According to the program office, the Reaper design is stable and all the expected design drawings have been released; however, the block 5 is still at risk for design changes until its upgrades are integrated and tested on the MQ-9 system. The transition from block 1 to block 5 increased the number of design drawings by about 20 percent, which program officials attribute primarily to the relocation of radio antennas to the wingtips and a redesign of the avionics bay. The program office conducted a critical design review for block 5 in January 2011. Program officials expect to close all the action items, the most significant of which involves testing the aircraft's airworthiness with the relocated antennas, by early 2012.

Production Maturity

The block 1 Reaper is in production and the production processes for block 5 are approaching the level of maturity recommended for low-rate initial production. The Air Force has contracted for 117 block 1 aircraft, about 30 percent of its total requirement, and has conducted several manufacturing reviews of the contractor's facilities and determined that the production capacity is sufficient to meet the expected demand.

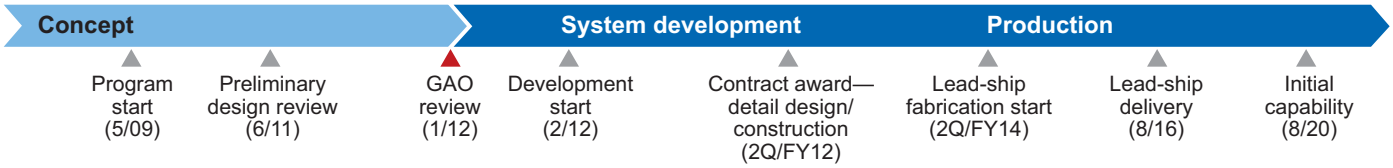
Other Program Issues

Since inception, the MQ-9 program has been challenged to meet the warfighter's changing needs. Quantities have increased dramatically and performance requirements continue to change. The program is currently incorporating several urgent operational requirements from the warfighter and officials expect other capabilities, such as the advanced signals intelligence payload sensor, to be added to the program. Although block 1 initial operational testing was done in 2008, problems with the radar and network prevented testers from evaluating the system's hunter and net-ready capabilities—two of its three key requirements. Testing of these capabilities was deferred until block 5 operational testing, which is currently planned for November 2013, a 1-year delay. The program also received approval to reduce or defer 12 required block 5 capabilities related to aircraft endurance, radar performance, and reliability, among other areas. According to the program office, none of these changes present a high operational risk for the system and some of them may be addressed in future upgrade efforts. According to program officials, the user is currently reevaluating its requirements and strategy for managing future Reaper upgrades. The increment II program, which included Small Diameter Bomb integration, automatic take-off and landing, deicing, and national airspace certification, was to begin in fiscal year 2012. According to program officials, the user is evaluating the feasibility of satisfying these requirements by upgrading the current configuration.



Program Office Comments

In commenting on a draft of this assessment, the Air Force stated that the program office is working to accelerate the low-rate initial production decision from July 2013 to June 2012. In order to accomplish this, the contractor has accelerated the first block 5 aircraft retrofit by 6 months and is focusing on developing software for the block 5 to allow for earlier verification. This accelerated date is also based upon tailoring of acquisition documents and schedule assumptions identified in the draft acquisition strategy that will require approval from the Office of the Secretary of Defense. The Air Force further stated that the increment II program is currently unfunded. The Air Force is reevaluating requirements and its strategy for future program upgrades.



2260 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Ship to Shore Connector (SSC)

The Navy's SSC is an air-cushioned landing craft intended to transport personnel, weapon systems, equipment, and cargo from amphibious vessels to shore. SSC is the replacement for the Landing Craft, Air Cushion (LCAC), which is approaching the end of its service life. The SSC will deploy in Navy well deck amphibious ships, such as the LPD 17 class, and will be used for assault and nonassault operations. It is expected to operate independent of tides, water depth, underwater obstacles, ice, mud, or beach conditions.

The SSC program has attained the level of knowledge about technology and design requirements needed to support the award of a detail design and construction contract for the lead craft, which is planned for the second quarter of fiscal year 2012. A 2010 technology readiness assessment found the program's one critical technology to be mature, and designated two technologies as watch items until a contractor selects the actual technologies to be used. According to the program office, the SSC is the first Navy-led ship design in 15 years and the Navy plans to provide two-dimensional extracted drawings from the design model to the contractor, who will then complete the design to prepare for production. The SSC is also being designed for affordability and the Navy has identified several performance tradeoffs to lower costs.

2261 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

SSC Program

Technology Maturity

The SSC program expects to award a detail design and construction contract in the second quarter of fiscal year 2012 with its one critical technology—the fire suppression system—mature. A 2010 technology readiness assessment by the Navy found this technology to be mature because the system had been extensively tested in an LCAC engine module modified to have similar characteristics to the SSC. In addition, the canisters that are part of the fire suppression system are commercially used and will not be modified for use on the SSC. Based on the technology readiness assessment, the Navy also decided that several other technologies should not be considered critical. For example, program officials stated the assessment did not identify the composite shaft as a critical technology because the composite material is already used on a Littoral Combat Ship. Other items, such as the gas turbine and the command, control, communications, computer, and navigation system were not designated critical because mature systems that meet all SSC requirements are available. However, these two technologies will remain on a watch list until the contractor selects the actual technologies to be used. According to program officials, there is a reasonable chance that the contractor could propose new technologies that require additional development if they have the potential to reduce cost.

Design Maturity

The Navy plans to stabilize the SSC design before the start of construction. According to program officials, after award of the detail design and construction contract, the Navy will provide two-dimensional extracted drawings from the design model to the contractor who will then complete the design of the craft for production. The Navy's request for proposal for detail design and construction requires the contractor to hold a production readiness review before the start of construction to demonstrate design maturity. Specifically, the contractor must demonstrate that both the functional design is 100 percent complete and the detailed production work packages are at least 95 percent complete before production start.

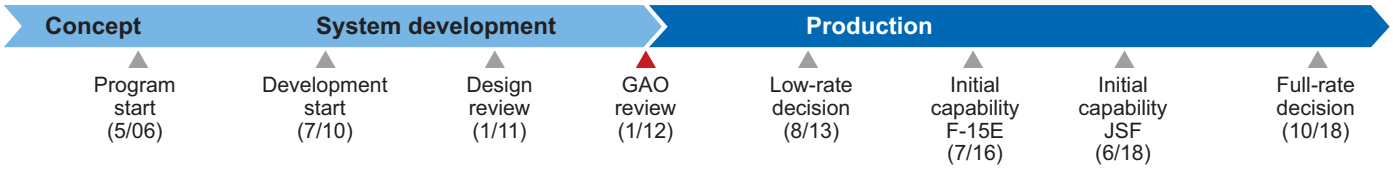
Other Program Issues

According to the program office, the SSC is the first Navy-led ship design in 15 years. The goal of the Navy-led design was to improve the capacity and maintainability of the SSC compared to the legacy LCAC, while reducing costs. To assist with this goal, the Navy conducted an analysis of the LCAC which focused on reducing total ownership cost while maintaining certain essential capabilities such as speed. Through this analysis, the Navy identified several performance trades. For example, the Navy identified a change to the cargo deck width which will allow for the use of nondevelopmental engines; this change is expected to lower life-cycle costs. The SSC is also expected to have greater lift, a lower fuel consumption rate, and less expected maintenance than the LCAC.

The Navy is conducting a full and open competition for the SSC detail design and construction contract. The Navy plans to award a fixed-price incentive contract for the detail design and construction of the lead craft, which is expected to be delivered by August 2016. The lead craft will be for testing and training and the contract is expected to have options for eight additional SSCs.

Program Office Comments

In commenting on a draft of this assessment, the Navy stated that the SSC is a technically mature, low risk program poised for successful entry into system development, program initiation, and detail design and lead craft construction contract award. The Navy also provided technical comments, which were incorporated as appropriate.



2262 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Small Diameter Bomb (SDB) Increment II

The Air Force's Small Diameter Bomb (SDB) Increment II is planned to provide attack capability against mobile targets in adverse weather from standoff range. It combines radar, infrared, and semiactive laser sensors in a multi-mode seeker to acquire, track, and engage targets. It uses airborne and ground data links to update target locations as well as GPS and an inertial navigation system to ensure accuracy. SDB II will be integrated with F-15E, Navy and Marine Corps' Joint Strike Fighter (JSF), and other aircraft, such as the F-22A.

Funding needed to complete:
R&D: $850.1 million
Procurement: $3,053.1 million
Total funding: $3,903.2 million
Procurement quantity: 17,000

Program Performance (fiscal year 2012 dollars in millions)

	As of 10/2010	Latest 08/2011	Percent change
Research and development cost	$1,644.8	$1,642.5	-0.1
Procurement cost	$3,057.3	$3,053.1	-0.1
Total program cost	$4,702.1	$4,695.6	-0.1
Program unit cost	$.274	$.274	-0.1
Total quantities	17,163	17,163	0.0
Acquisition cycle time (months)	72	72	0.0

The SDB II program completed its critical design review in January 2011 with a stable design, but without fully maturing its critical technologies or demonstrating that the design can perform as expected. As a result, the risk of design changes remains. A postdesign review identified several risks related to weapon effectiveness verification, target classification, seeker reliability, and JSF integration. The program office is working to address each of these risks and plans to begin evaluating the reliability and performance of the weapon through flight testing in March 2012. However, the program's biggest risk—integration with the JSF—will not be resolved until after production begins. The program faces a shortfall in funding, and program officials are considering modifying the fixed-price incentive contract or the current scope of work to align with the funding profile.

2263 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

SDB II Program

Technology Maturity

The SDB II program entered system development in July 2010 with all four of its critical technologies—the target classifier, multimode seeker, net-ready data link, and payload (warhead/fuze)—nearing maturity. Although the program has completed its critical design review, it is just beginning to further demonstrate these technologies through subsystem testing. According to the program office, subsystem testing is progressing well. Prototype testing is scheduled to begin in February 2012 and will demonstrate the weapon's ability to interface with the required aircraft and the seeker's performance.

Design Maturity

The SDB II design is currently stable, but it has not been demonstrated using a prototype to show that it will perform as expected. The risk of design changes will remain until the design shows it can meet requirements and other risks are addressed. The program completed its critical design review in January 2011 with 97 percent of its design drawings releasable. A postdesign review identified several risks related to weapon effectiveness verification, target classification, seeker reliability, and integration with the JSF. The program office is working to address each of these risks. In addition, the SDB II is scheduled to begin flight testing on the F-15E in March 2012; according to the program office, these tests will help to increase its confidence in the reliability and performance of the weapon. The SDB II program plans to conduct 11 free-flight test events prior to obtaining approval to begin production, which is currently scheduled to occur in August 2013.

According to the postdesign review and program officials, the top risk for the SDB II program is integration of the weapon with the JSF. The SDB II, which is carried in the JSF's internal weapons bay, was designed to operate in the environment specified in JSF design documents. However, the weapons bay environment has not been validated through testing. If the JSF cannot meet its design specifications, then the SDB II program may not meet its requirements for weapon effectiveness or availability on that aircraft; it might also have to consider design changes. This issue will not be resolved prior to the SDB II's planned August 2013 production decision and could affect the program's full-rate production in 2018. SDB II integration on the JSF is planned to begin in fiscal year 2015 and operational testing is planned for 2017.

Production Maturity

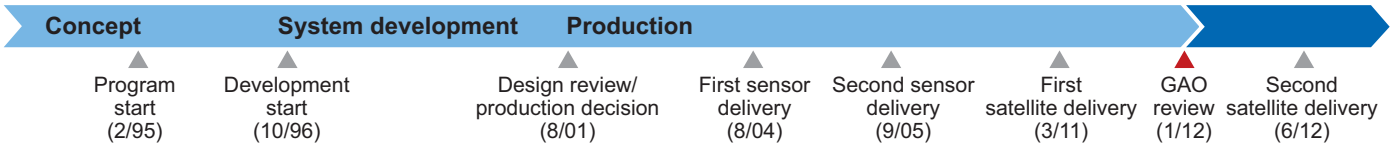
The SDB II program plans to take several steps to demonstrate the maturity of its manufacturing processes prior to beginning production. The program will demonstrate its critical manufacturing processes on a pilot production line and demonstrate that the system will work as intended in a reliable manner by testing a fully configured production-representative prototype.

Other Program Issues

The SDB II program office is managing a $53 million funding shortfall in fiscal year 2011, which could have programmatic and contractual implications. The SDB II contract is an incrementally funded, fixed-price incentive contract, and program officials stated that the funding shortfall could mean that the next part of the work will have to be deferred or the contract will need to be renegotiated or terminated.

Program Office Comments

In commenting on a draft of this assessment, the Air Force and Navy provided technical comments, which were incorporated as appropriate.



2264 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Space Based Infrared System (SBIRS) High Program

The Air Force's SBIRS High satellite system is being developed to replace the Defense Support Program and perform a range of missile warning, missile defense, technical intelligence, and battlespace awareness missions. SBIRS High will consist of four satellites in geosynchronous earth orbit (GEO), two sensors on host satellites in highly elliptical orbit (HEO), two replenishment satellites and sensors, and fixed and mobile ground stations. We assessed the space segment and made observations about the ground segment.

Program Essentials

Prime contractor: Lockheed Martin
Program office: El Segundo, CA
Funding needed to complete:
R&D: $2,131.3 million
Procurement: $3,599.4 million
Total funding: $5,743.9 million
Procurement quantity: 2

Program Performance (fiscal year 2012 dollars in millions)

	As of 10/1996	Latest 07/2011	Percent change
Research and development cost	$4,376.3	$11,586.3	164.7
Procurement cost	$0.0	$6,429.3	NA
Total program cost	$4,596.5	$18,266.7	297.4
Program unit cost	$919.301	$3,044.443	231.2
Total quantities	5	6	20.0
Acquisition cycle time (months)	86	TBD	NA

The 1996 data show no procurement cost as the Air Force planned to use research and development funds to buy all five satellites. The cost of the two HEO replenishment sensors is not included in either column.

The first SBIRS satellite was launched in May 2011—roughly 9 years later than planned—however, it lacks some key capabilities. The satellite was launched without a fully developed ground system or the flight software needed to automatically recover if an unforeseen failure occurs. According to program officials, the ground system will not be able to meet all of its operational requirements until at least 2018. The satellite recovery software will be uploaded to the satellite on-orbit once it is complete, expected in August 2012. The first satellite has begun on-orbit testing, but its planned operational certification in late 2012 will likely be delayed to early 2013. The program expects the cost of the third and fourth satellites to grow significantly. A new program baseline, which includes revised cost estimates and satellite and ground system delivery milestones, awaits DOD approval.

2265 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

SBIRS High Program

Technology, Design, and Production Maturity

According to the SBIRS program office, the system's critical technologies are mature, its design is stable, and its manufacturing processes have been proven; however, the program continues to experience quality problems that have required rework on the first two satellites. Functional testing on the first satellite in 2009 revealed solder fractures on some hardware components and testing on the second satellite in 2011 has uncovered anomalies and erratic performance on similar components. In both cases, some rework has been required to the satellites; however, program officials do not expect that these issues will result in significant cost growth or schedule delays. System-level testing on the second satellite has begun and the program expects it to be delivered in June 2012. Its launch date has yet to be determined.

The SBIRS program plans to make slight changes to the design of its two HEO replenishment sensors, addressing parts obsolescence and electromagnetic interference issues that affected the operation of its first two sensors. Replenishment sensors are scheduled for delivery and integration onto host satellites in fiscal years 2012 and 2015.

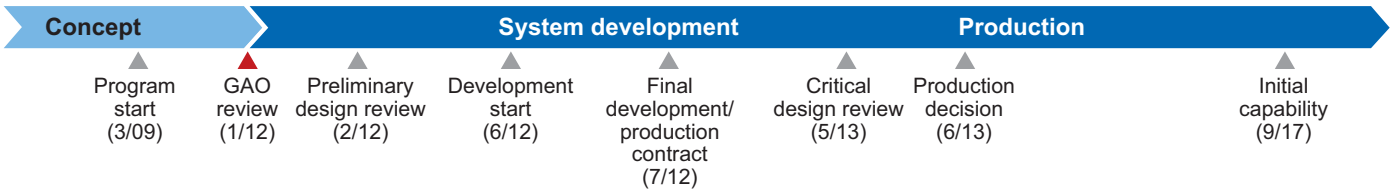
Other Program Issues

The first GEO satellite, and likely second, will be launched and operating on-orbit before the program can fully leverage the satellites' capabilities. The SBIRS program opted to launch the first GEO satellite in May 2011 before the ground system, which processes data from the satellite's infrared sensors, was fully developed. According to the program office, it did so to provide some capability to users sooner. Ground system development has proved more difficult than anticipated and officials say the system will not be able to fully meet its operational requirements until at least 2018. In the meantime, ground system capabilities will be fielded incrementally. According to the Defense Contract Management Agency, the flight software development effort is still experiencing challenges and delays. The first satellite was launched without all of the planned flight software functionality, including, for example, a capability that allows the satellite to automatically recover without ground intervention from a "fault-mode" in the event of an unforeseen failure. The program intends to upload this software to the first satellite on-orbit after it completes development. According to the Defense Contract Management Agency, on-orbit check out activities, for example, system-level testing and calibration, are currently 6 weeks behind schedule, which could delay the operational certification of the first satellite, planned for late 2012.

According to the SBIRS program, production of the third and fourth satellites may experience significant cost growth and schedule delays due to development challenges, test failures, and technical issues. The Air Force is projecting a cost overrun of $438 million and 1-year delay for these two satellites. The program plans to award a sole-source contract to the same prime contractor to build the fifth and sixth satellites. The SBIRS program has revised its acquisition program baseline, which will include revised cost estimates and new satellite and ground system delivery milestones, but DOD has yet to approve it.

Program Office Comments

In commenting on a draft of this assessment, the program office stated that the first satellite launched with all the software needed to support vehicle health and safety. Sensors on the first satellite are collecting higher-quality data than expected. The satellite is moving to its operational location, and officials expect trial operations to last from November 2012 to January 2013. The follow-on production contract is delivering flight hardware, but is experiencing cost and schedule pressure due to parts obsolescence and technical issues. Officials attribute this to an 8-year production gap between the first two satellites and the third and fourth. The revised acquisition program baseline is final as of January 2012. The acquisition strategy for the fifth and sixth satellites is pending, and the program is seeking approval to release requests for proposals and contract awards. The program office also provided technical comments, which were incorporated as appropriate.



2266 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Space Fence

The Air Force's Space Fence will be a new system of large ground-based radars that replaces the Air Force's aging Space Surveillance System. It will use higher radio frequencies to detect and track smaller Earth-orbiting objects. The system will consist of two geographically dispersed radars to help ensure effective space surveillance coverage for low inclinations. The system's enhanced capabilities are expected to significantly increase the number of orbiting objects detected and tracked.

In May 2010, the program office estimated the Space Fence's total cost would be over $3 billion; an updated estimate has not been provided.

The Space Fence program office expects to have gained key knowledge about its technology and requirements before it enters system development in June 2012. Its four critical technologies are nearing maturity and it will hold a preliminary design review prior to development start. The current technology development phase involves multiple contractors and competitive prototyping demonstrations. The program plans to award a single contract for system development and production in July 2012. The first Space Fence radar site is scheduled to provide an initial operational capability by the end of fiscal year 2017—2 years later than originally planned—and the Air Force will be required to support the existing surveillance system longer than anticipated. A new data-processing system is also being developed by a separate program to accommodate the increased volume of data from Space Fence.

Attainment of Product Knowledge

Projected as of January 2012

Space Fence Program

Technology Maturity

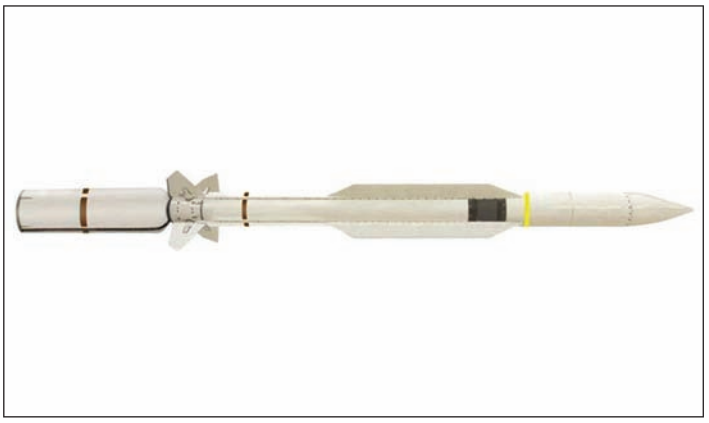
The Space Fence program expects its four critical technologies to be nearing maturity before it enters system development in June 2012. The technologies include a software algorithm for estimating orbits and several radar technologies—a high-efficiency power amplifier; low-cost distributed receiver; and scalable digital beam former that allows antennas to work in concert to create sufficient power to conduct the space surveillance and tracking mission. Mature backup technologies that have potentially higher acquisition or operating costs also exist, but program officials do not believe they will be needed. According to the program, the Space Fence will be one of the largest phased array radars ever built, and the key risks are related to its size and the integration of technology components into a viable system at an affordable cost. According to the program office, its technology development efforts, which involve multiple contractors, will allow the program to thoroughly examine the contractors' designs and their associated costs, while reducing technical risk and improving confidence in the producibility of the key technologies and components.

Other Program Issues

The Space Fence program maintained competition through technology development and plans to competitively award a single contract for system development and production. In June 2009, the Air Force competitively awarded three $30 million firm fixed-price contracts to begin technology development, one of which was subsequently terminated after a reduction in program funding. After a full and open competition, the two other contractors were each awarded another contract in January 2011, for a maximum of $214 million, to continue technology development. The Space Fence program plans to conduct a full and open competition and award a single contract for system development and production in July 2012. According to the program office, the release of the request for proposal for this contract has been delayed from December 2011 to April 2012 because DOD now requires a program review to be held before its release. However, the program office believes the contract can still be awarded on schedule. The program office plans to award a firm fixed-price contract for system development activities through the planned May 2013 critical design review, with options for all subsequent efforts, including radar production.

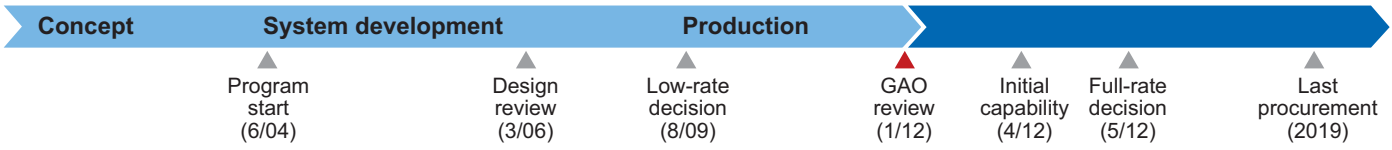
The first Space Fence radar site is scheduled to provide initial operational capability by the end of fiscal year 2017—2 years later than planned—because current program funding levels do not support an earlier date. As a result, the Air Force will be required to support the existing surveillance system longer than anticipated. It is currently assessing ways to keep the system in operation until the Space Fence is ready. The second Space Fence site will provide a full operational capability by 2020.

A new data-processing capability is being developed by a separate program to accommodate the increased volume of data from Space Fence. According to the Space Fence program office, this program is currently being restructured and should be fielded in time to support Space Fence.



Program Office Comments

In commenting on this draft, the program office noted that it generally concurred with our assessment. The program noted that a technology readiness assessment is ongoing and the Space Fence preliminary design review is on schedule to be completed by the end of February 2012. The program also provided technical comments, which were incorporated as appropriate.



2268 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Standard Missile-6 (SM-6) Extended Range Active Missile (ERAM)

The Navy's Standard Missile-6 (SM-6) is a surface-to-air missile launched from Aegis ships. It is designed to provide ship self-defense, fleet defense, and theater air defense against aircraft, ships, and missiles at various altitudes over land and sea. It will provide an over-the-horizon engagement capability and improved capabilities at extended ranges by combining legacy Standard Missile and Advanced Medium-Range Air-to-Air Missile (AMRAAM) technology. We assessed SM-6 block 1. Follow-on blocks will be developed to meet future threats.

Source: Raytheon Missile Systems.

Program Essentials

Prime contractor: Raytheon Missile Systems
Program office: Arlington, VA
Funding needed to complete:
R&D: $7.6 million
Procurement: $4,808.9 million
Total funding: $4,816.6 million
Procurement quantity: 1,111

Program Performance (fiscal year 2012 dollars in millions)

	As of 07/2004	Latest 12/2010	Percent change
Research and development cost	$1,073.8	$973.5	-9.3
Procurement cost	$4,626.4	$5,323.2	15.1
Total program cost	$5,700.2	$6,296.7	10.5
Program unit cost	$4.750	$5.247	10.5
Total quantities	1,200	1,200	0.0
Acquisition cycle time (months)	75	94	25.3

The SM-6's highly concurrent testing and production strategy puts the program at increased risk of cost growth and schedule delays. The program has 89 missiles under contract, but it has not yet demonstrated that its manufacturing processes are in control or the missile is reliable, suitable, and effective in its operational environment. The program has experienced numerous developmental and operational test failures. Program officials stated that root causes have been identified and corrective actions will be addressed during follow-on testing. The program plans to request approval to enter full-rate production in May 2012; and the Under Secretary of Defense for Acquisition, Technology and Logistics will have to determine whether additional flight testing is needed, or if the current risks on the program will continue to be carried forward into full-rate production.

SM-6 Program

Technology and Design Maturity

According to the program office, all SM-6 critical technologies are mature and its design is stable; however, the program is still at risk of late design changes because of repeated test failures. The program obtained approval to conduct limited developmental testing because the risk of integrating the legacy AMRAAM missile seeker with the Standard Missile was perceived to be low. However, over half of the SM-6's at-sea developmental flight tests experienced anomalies or resulted in failure with multiple issues attributed to these legacy components. A May 2011 operational test readiness assessment concluded that the program faced a high risk of failure in operational testing and recommended additional developmental testing. The program proceeded with operational testing in June 2011 and the missile failed 5 of 12 tests. According to program officials, all failures have had root causes discovered, and corrective actions will be verified during follow-on operational testing, which is scheduled to occur after the program's planned May 2012 full-rate production decision. The Navy's operational test organization plans to issue its assessment of operational testing by April 2012 to support the full-rate production review.

Production Maturity

The SM-6 program has proven out its production processes, but has not yet demonstrated that its critical processes are in control or that the missiles being produced perform reliably. According to the program, the sample size needed for measuring process control will not be achieved until 2014.

Other Program Issues

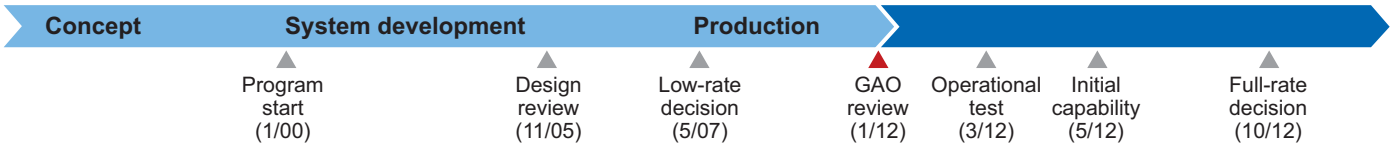
The SM-6's highly concurrent testing and production strategy puts the program at increased risk of cost growth and schedule delays. The program has made a significant investment before demonstrating that the design meets performance requirements and that the missile is reliable, suitable, and effective in its operational environment. In 2009, the program obtained approval from the Under Secretary of Defense for Acquisition, Technology and Logistics to begin low-rate production of up to 19 missiles before completing developmental testing. To minimize risks, the Under Secretary required the program to complete developmental testing and obtain approval prior to awarding additional contracts. The Under Secretary subsequently approved the award of two additional low-rate production contracts before this testing was complete. After numerous developmental test failures, the program carried a significant level of risk into operational testing where the high failure rate continued. The program plans to seek approval for full-rate production in May 2012 and to award a full-rate production contract with options through fiscal year 2016. The Under Secretary will have to determine whether additional flight testing is needed, or if the risks on the program will continue to be carried forward into full-rate production. Further, multiple SM-6 capabilities will not be tested until full-rate production is well underway. According to officials, the program plans to have 387 of 1,200 missiles under contract by the end of fiscal year 2014. This is before the SM-6 will be tested with the Naval Integrated Fire Control–Counter Air System, which enables its over-the-horizon capabilities.

Program Office Comments

In commenting on a draft of this assessment, the Navy disagreed with our assertions that the program is at risk of design changes because of repeated test failures; that the program has not demonstrated that its critical processes are in control and that the missile meets performance requirements; and that multiple capabilities will not be tested until full-rate production is well underway. According to program officials, the missile design is mature and stable, and all flight failures and anomalies are understood with corrective actions in place or in progress. The program office also provided technical comments, which were incorporated as appropriate.

GAO Response

According to program officials, the SM-6 design is stable; however, the program has not yet demonstrated that the system is reliable, suitable, and effective in its operational environment. Our reviews of DOD weapon systems confirm that production costs are minimized when a fully integrated, capable prototype is demonstrated to show that the system will work as intended in a reliable manner.



2270 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Vertical Take-off and Landing Tactical Unmanned Aerial Vehicle (VTUAV)

The Navy's VTUAV is intended to provide real-time imagery and data in support of intelligence, surveillance, and reconnaissance missions. A VTUAV system is composed of up to three air vehicles with associated sensors, two ground control stations, one recovery system, and spares and support equipment. The air vehicle is launched and recovered vertically, and operates from ships and land. The VTUAV is being designed as a modular, reconfigurable system that supports various operations, including surface, antisubmarine, and mine warfare.

Funding needed to complete:
- R&D: $16.2 million
- Procurement: $1,582.8 million
- Total funding: $1,599.0 million
- Procurement quantity: 145

Program Performance (fiscal year 2012 dollars in millions)

	As of 12/2006	Latest 09/2011	Percent change
Research and development cost	$598.0	$682.1	14.1
Procurement cost	$1,682.6	$1,933.2	14.9
Total program cost	$2,615.4	$2,615.4	0.0
Program unit cost	$14.776	$14.945	1.1
Total quantities	177	175	-1.1
Acquisition cycle time (months)	104	148	42.3

The VTUAV program continues to experience delays as a result of issues identified during testing. According to the program, it has made hardware and software changes to address the issues and improve the reliability, maintainability, and availability of the air vehicle and ground control station. The program has delayed the planned start of operational testing to March 2012 and could have difficulty demonstrating certain aspects of the system's effectiveness and suitability. DOD's independent test organization and military commanders have stated that the system provides a valuable capability, but the test organization has expressed concerns about data link reliability and launch delays. The program is planning several aircraft upgrades, including a multimode maritime radar, forward-firing weapon, and larger airframe to improve endurance, payload, and carrying capacity.

2271 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

VTUAV Program

Technology Maturity

The VTUAV program did not identify any critical technologies. According to the program office, it relies on common, mature technologies.

Design Maturity

The VTUAV design appears stable and the program has released all its expected drawings; however, the program has made a number of software and hardware changes to correct issues identified in developmental testing. According to the program, the main issues in testing were related to the reliability, maintainability, and availability of the air vehicle and the control station. Several critical components experienced unanticipated failures, but were corrected with software or hardware improvements. As a result of the problems highlighted during developmental testing, the VTUAV program delayed the planned start of operational test and evaluation until March 2012. The program plans to reach initial operational capability in May 2012 and enter full-rate production in October 2012—more than 2 years later than planned.

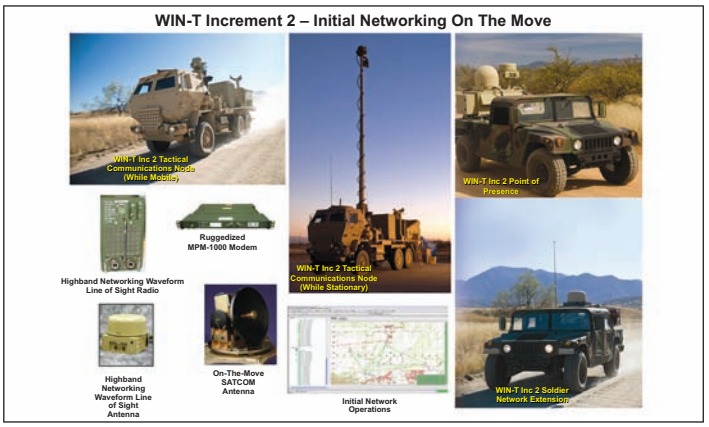
Production Maturity

The VTUAV program's production processes have been demonstrated, but we could not assess whether its critical processes are in control. The program does not collect data on statistical process controls or assess process capabilities using manufacturing readiness levels. As of fiscal year 2011, the program planned to convert eight Army aircraft bought under the Future Combat Systems into Navy VTUAV aircraft.

Other Program Issues

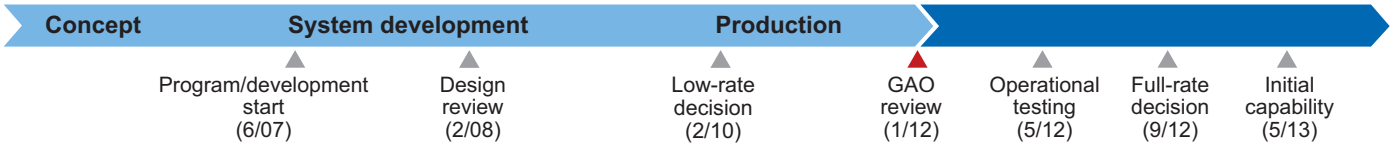
The VTUAV program may have difficulty demonstrating its effectiveness and suitability in operational testing. An early fielding report by the Director, Operational Test and Evaluation, concluded that the VTUAV can be a valuable intelligence-gathering asset, but forces should not depend on it to provide time-sensitive support to ground forces because of the fragile nature of the data link and frequent launch delays. According to the report, a primary reason for these delays is multiple ground control station configurations, which makes it difficult for the program to identify and correct the root causes of problems and replicate failure modes to assist the operator in troubleshooting issues. According to the program office, the VTUAV's deployments aboard the USS *Halyburton* and in Afghanistan have demonstrated the military utility of the system, and the operational commands in Afghanistan have requested doubling the VTUAV capability there. The Navy recently lost a VTUAV aircraft in Libya due to enemy actions.

The VTUAV program is planning several upgrades of the system. For example, the program is planning to acquire a multimode maritime radar and forward-firing weapon for installation on the aircraft using a rapid acquisition process that enables the capabilities to be delivered to the warfighter quickly. Both capabilities will be acquired as a part of the current program and will undergo a formal quick-reaction assessment in fiscal year 2013 prior to their planned deployment. In addition, the program plans to buy 28 upgraded aircraft with a larger airframe to improve endurance, payload, and future carrying capacity.



Program Office Comments

The program office concurred with this assessment.



2272 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Warfighter Information Network-Tactical (WIN-T) Increment 2

WIN-T is the Army's high-speed and high-capacity backbone communications network. WIN-T connects Army units with higher levels of command and provides the Army's tactical portion of the Global Information Grid. WIN-T was restructured following a March 2007 Nunn-McCurdy unit-cost breach of the critical threshold, and will be fielded in four increments. The second increment will provide the Army with an initial networking on-the-move capability.

Program Essentials

Prime contractor: General Dynamics C4 Systems, Inc.
Program office: Aberdeen Proving Ground, MD
Funding needed to complete:
R&D: $29.3 million
Procurement: $4,803.2 million
Total funding: $4,832.5 million
Procurement quantity: 2,390

Program Performance (fiscal year 2012 dollars in millions)

	As of 10/2007	Latest 12/2010	Percent change
Research and development cost	$238.6	$279.2	17.0
Procurement cost	$3,469.8	$5,773.5	66.4
Total program cost	$3,708.4	$6,052.7	63.2
Program unit cost	$1.959	$2.127	8.6
Total quantities	1,893	2,846	50.3
Acquisition cycle time (months)	50	71	42.0

The WIN-T Increment 2 entered production in February 2010 with mature critical technologies, a stable design, and production processes that had been demonstrated, but were not in control. The program's assessment of its manufacturing readiness level indicates that it has not yet demonstrated the capability recommended by DOD guidance to begin full-rate production, which is currently planned for September 2012. The program has been working to address performance and reliability shortfalls revealed in a March 2009 limited user test. According to the program office, production qualification testing has been successful, and the program believes it will demonstrate the required performance and reliability during initial operational testing, which is scheduled to begin in May 2012.

2273 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

WIN-T Increment 2 Program

Technology Maturity

All 15 WIN-T Increment 2 critical technologies were mature by its February 2010 production decision. In November 2009, the Director, Defense Research and Engineering, concurred with an independent review team's assessment of the program, noting that tests conducted by the Army show that each of WIN-T Increment 2's critical technologies have been demonstrated in a realistic environment.

Design Maturity

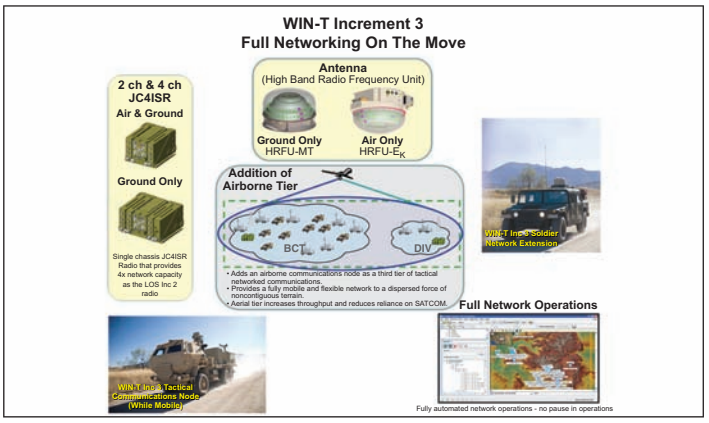
According to the WIN-T program, it has integrated and tested its key technologies and subsystems, which demonstrates that the system's design is capable of working as intended. The program office does not track the other metric we use to measure design maturity—the number of releasable drawings—because WIN-T is primarily an information technology integration effort. Instead, design performance is measured through a series of component, subsystem, configuration item, and network-level test events designed to demonstrate performance at increasing levels of system integration, and design stability is measured through problem-tracking report trends.

Production Maturity

The WIN-T program began production in February 2010 with manufacturing processes that had been demonstrated on a pilot production line, but were not in control. The program's assessment of its manufacturing readiness level does not indicate that its production processes are in statistical control or that the program has demonstrated that the capability recommended by DOD guidance is in place to begin full-rate production, which is currently planned for September 2012. According to the WIN-T program, it uses commercially available products and does not have any critical manufacturing processes.

Other Program Issues

According to the WIN-T program, it has addressed the deficiencies identified in its March 2009 limited user test and is prepared to begin initial operational testing on schedule in May 2012. During the limited user test, WIN-T Increment 2 failed to demonstrate the ability to support mobile operations as well as the required capabilities in forested terrain. WIN-T Increment 2 operational effectiveness was degraded because the program's concept of operations, organizational structure, and manning were not adequate to operate and troubleshoot the network. Further, the test concluded that the WIN-T Increment 2 did not meet its operational reliability requirements because three critical components demonstrated poor reliability. After this test, DOD's Director, Operational Test and Evaluation, recommended that the Army improve the performance of the Increment 2 waveforms, provide greater training to soldiers, refine its tactics and manning levels for Increment 2, and aggressively pursue a reliability growth program for WIN-T Increment 2 components to ensure its success in initial operational testing. According to the program office, production qualification testing conducted by the contractor in early 2011 indicated that the system is on target to meet its minimum performance requirements. Reliability issues were identified during that testing, but the program believes that each of the program's configuration items is meeting its reliability growth target, and that the program will demonstrate required performance and reliability during upcoming initial operational testing.



Program Office Comments

In commenting on a draft of this assessment, the Army provided technical comments, which were incorporated as appropriate.

2274 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Warfighter Information Network-Tactical (WIN-T) Increment 3

WIN-T is the Army's high-speed and high-capacity backbone communications network. WIN-T connects Army units with higher levels of command and provides the Army's tactical portion of the Global Information Grid. WIN-T was restructured following a March 2007 Nunn-McCurdy unit-cost breach of the critical threshold, and will be fielded in four increments. The third increment will provide the Army a full networking on-the-move capability.

Program office: Aberdeen Proving Ground, MD
Funding needed to complete:
R&D: $890.3 million
Procurement: $11,649.1 million
Total funding: $12,539.4 million
Procurement quantity: 3,168

Program Performance (fiscal year 2012 dollars in millions)

	As of 05/2009	Latest 12/2010	Percent change
Research and development cost	$2,687.4	$2,222.3	-17.3
Procurement cost	$13,680.3	$11,649.1	-14.8
Total program cost	$16,367.7	$13,871.4	-15.3
Program unit cost	$4.701	$4.325	-8.0
Total quantities	3,482	3,207	-7.9
Acquisition cycle time (months)	165	187	13.3

The WIN-T Increment 3 program will not demonstrate the maturity of all its critical technologies until its planned April 2015 production decision. Three of the program's 20 critical technologies are currently mature and 15 are nearing maturity. Of the two remaining technologies, one was rated as nearing maturity by an independent review team; but in 2009, the Director, Defense Research and Engineering, concluded that the technology's ambiguous requirements made it difficult to state whether it had been adequately demonstrated. The Army has since revisited its requirements. According to the Army, the other technology—a cryptographic device—will be demonstrated by its system-level design review. The WIN-T Increment 3 schedule is likely to be negatively affected by an almost 40 percent reduction in planned funding for fiscal year 2012.

2275 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

WIN-T Increment 3 Program

Technology Maturity

The WIN-T Increment 3 program will not demonstrate the maturity of all of its critical technologies in a realistic environment until its planned April 2015 production decision. An April 2009 review of the Army's technology readiness assessment for WIN-T Increment 3 by the Director, Defense Research and Engineering (DDR&E), concluded that, of the program's 20 critical technologies, 3 were mature, 15 were nearing maturity, and 2—the Quality of Service Edge Device (QED) and High Assurance Internet Protocol Encryptor (HAIPE) version 3.X—could not be formally rated.

The Army has rated the QED as nearing maturity; however, DDR&E concluded that this technology had ambiguous requirements that made it difficult to state whether it had been adequately demonstrated. DDR&E noted that while the Army had demonstrated that the QED technology met requirements under most conditions, in one stressing scenario, it did not. DDR&E representatives have stated in the past that it is unlikely that any network can meet this requirement in all environments. Since the QED technology was shown to be robust and capable of meeting its requirement in most scenarios, DDR&E recommended that the Army clarify the user's requirements for this technology by its system-level design review, currently scheduled for August 2014. According to a program official, the Army's Training and Doctrine Command has revisited the user requirements; however, it will still wait to reassess the QED's maturity until the system-level design review. According to the Army, the QED technology has been demonstrated in recent WIN-T Increment 2 production qualification tests. It is anticipated that the technology used in WIN-T Increment 2 can be applied to WIN-T Increment 3 with little or no changes to the existing functionality.

HAIPE version 3.X was not available to be assessed at the time of DDR&E's review; however, a National Security Agency (NSA) official has since said it is mature. HAIPE is a device that encrypts and encapsulates Internet protocol packets so that they can be securely transported over a network of a different security classification. DDR&E has notified the Army that the maturity of the HAIPE version 3.X technology should be established to DDR&E's satisfaction before it is transitioned into WIN-T Increment 3. HAIPE 3.1 is currently being used in the WIN-T Increment 2 network. According to the Army, this version has introduced some network efficiencies, but the HAIPE version 4.1 will be needed to support the full set of network efficiencies required by WIN-T Increment 3. The maturity of these critical technologies will be demonstrated in a realistic environment by the April 2015 production decision. The Army will clarify the user's requirements for these technologies by its system-level design review, currently scheduled for October 2012.

Other Program Issues

The WIN-T Increment 3 schedule is likely to be negatively affected by reductions in its planned funding for fiscal year 2012. The joint explanatory statement accompanying the Department of Defense Appropriations Act, 2012, recommended $183 million for WIN-T Increment 3 research, development, test, and evaluation funding, a 40 percent reduction from the budget request of $298 million. The Army explained that as a result of this reduction, the program has modified the program strategy to reflect a two-phased approach. The initial aerial tier capability is planned for the low-rate production decision in fiscal year 2015 and the full aerial tier capability supporting full networking on-the-move is planned for the full-rate production decision in fiscal year 2018.

Program Office Comments

In commenting on a draft of this assessment, the Army provided technical comments, which were incorporated as appropriate.

2276 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Advanced Extremely High Frequency (AEHF) Satellite

The Air Force's AEHF satellite system will replenish the existing Milstar system with higher-capacity, survivable, jam-resistant, worldwide, secure communication capabilities for strategic and tactical warfighters. The program includes six satellites and a mission control segment. Terminals used to transmit and receive communications are acquired separately by each military service. AEHF is an international program that includes Canada, the United Kingdom, and the Netherlands.

Source: © 2009 Lockheed Martin Corporation. All rights reserved.

Current Status

The first AEHF satellite was launched in August 2010 and was expected to reach its planned orbit in about 3 months, but a propulsion system anomaly delayed the satellite's arrival on orbit. The Air Force used other propulsion systems designed to control and reposition the satellite to raise it into its intended orbit, a process it estimated would take 10 to 12 months. However, the program office, in conjunction with the user community, decided to extend the satellite's ascent to save fuel for on-orbit operations and the satellite reached its planned orbit in late October 2011. The satellite will go through about a 100-day checkout and testing period before it becomes available for operations.

The launch of the second and third AEHF satellites was delayed after the problems with the first satellite were discovered, but they have now been cleared for flight. The program office and prime contractor determined the propulsion system anomaly on the first satellite was most likely caused by debris in the system's oxidizer fuel line introduced during the manufacturing process. The second and third satellites, which were already built, were tested to confirm there were no similar blockages. The estimated launch dates for these satellites are April 2012 and the fall of 2013 respectively. The fourth satellite is under contract and is scheduled to be available for launch in 2017. The Air Force plans on procuring the fifth and sixth satellites using a block-buy acquisition strategy intended to produce savings that would be reinvested in research and development for follow-on systems. The Air Force requested congressional approval for the block buy in its fiscal year 2012 budget request. The last two satellites are tentatively expected to be available for launch in 2018 and 2019. In 2009, DOD announced the cancellation of the Transformational Satellite Communications System—the planned follow-on to AEHF. In June 2011, DOD commissioned an internal study to address follow-on programs for AEHF and the Wideband Global SATCOM communications programs, which will lead to a subsequent analysis of alternatives.

Estimated Total Program Cost: $14,082.8 million
Research and development: $7,759.4 million
Procurement: $6,323.4 million
Quantity: 6

Next Major Program Event: Launch of second AEHF satellite, April 2012

Program Office Comments: In commenting on a draft of this assessment, the Air Force noted that satellite command and control was transitioned from Milstar to the AEHF mission control segment in June 2011. The Air Force also provided technical comments, which were incorporated as appropriate.

2277 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

B-2 Defensive Management System (DMS) Modernization

The Air Force's B-2 DMS modernization program is expected to upgrade the aircraft's 1980s-era analog defensive management system to a digital capability. The program is intended to improve the frequency coverage and sensitivity of the electronic warfare suite, update pilot displays, and enhance in-flight replanning capabilities for avoiding unanticipated air defense threats. It is also expected to improve the reliability and maintainability of the DMS system and, as a result, the B-2's readiness rate.

Source: U.S. Air Force.

Current Status

The B-2 DMS program was approved to enter technology development in August 2011. On the basis of an analysis of alternatives, the Air Force elected to fully modernize the B-2 DMS using a single-step rather than an incremental acquisition approach to deliver the intended capability. Using a single-step acquisition strategy can increase risk on a program because it can add complexity to design and software efforts. The B-2 DMS program is also implementing a rapid acquisition initiative, which it believes can reduce its acquisition cycle from 10 to 7 years and lower its cost by over $500 million. The initiative includes: (1) conducting early software prototyping; (2) reducing the time required for flight testing by utilizing a flying test bed for risk reduction, improving test-range access, and expediting test data analysis; and (3) improving installation times by using antennas that conform to the B-2 design. The program's current funding plan and schedule do not reflect the anticipated benefits of the initiative. According to the B-2 program office, it expects DOD to assess the program's progress in achieving the initiative's objectives before the start of system development, and will adjust the program's cost and schedule targets accordingly.

The B-2 DMS program office has identified five critical technologies, three of which are mature or nearing maturity. The program expects the two other technologies—the low-observable antennas for the B-2 leading edges and associated receivers—to be nearing maturity by the start of system development. The program does not plan to develop prototypes of the full B-2 DMS, but instead plans to prototype the antenna subsystems, which it believes presents a key technical risk. The program also identified the stringent nuclear hardening requirements of the B-2 design as a technical risk.

Estimated Total Program Cost: $1,979.9 million
Research and development: $1,259.1 million
Procurement: $720.8 million
Quantity: 20

Next Major Program Event: System development start, fourth quarter fiscal year 2013

Program Office Comments: The program was provided a draft of this assessment and had no comments.

2278 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

B-2 Extremely High Frequency SATCOM Capability, Increment 2

The Air Force's B-2 EHF SATCOM is a satellite communication system designed to upgrade the aircraft's ultra-high-frequency system to ensure secure communication. The system has three increments. Each one is expected to be a major defense acquisition program. Increment 2 is designed to provide connectivity by adding low-observable antennas and radomes to the aircraft. It is also intended to include separate, nonintegrated Family of Advanced Beyond Line-of-Sight Terminals (FAB-T) and related hardware integral to the EHF SATCOM capability.

Source: U.S. Air Force.

Current Status

The B-2 EHF Increment 2 program is in technology development, but some work on the program has stopped. The program began a component advanced development effort in March 2008 that includes systems engineering, requirements analysis, technology maturation, and preliminary design activities. In August 2011, program officials told us that work related to FAB-T was halted because that program was experiencing FAB-T delivery delays. In October 2011, work on the active electronically scanned array (AESA) antenna system also ceased because of funding uncertainties for fiscal year 2012. While work on the antenna system resumed in December 2011, this was the latest in a series of delays for the Increment 2 program. The program's schedule before work stopped showed system development beginning in April 2013—3 years later than first planned—and production starting after the U.S. Strategic Command's identified need date of 2017.

If and when the B-2 EHF Increment 2 program fully resumes, FAB-T will continue to pose a significant risk. Program officials told us that a terminal, like FAB-T, is significant to the Increment 2 program because it handles the aircraft's communication with EHF satellites, analogous to how a phone or cable modem handles communication with the internet. The Air Force and the Increment 2 program office are looking at ways to mitigate the risk. Program officials told us the Air Force began exploring a potential alternate source for FAB-T in 2011, and the Increment 2 program office was investigating a different approach to secure communication that would not involve the EHF frequency or FAB-T.

In addition to FAB-T, antenna technology maturation is a program risk. The AESA antenna system the program is developing has several critical technologies that are still immature. The program does have a plan to mature these technologies prior to beginning system development in April 2013, but it does not have a backup antenna technology option should AESA not mature as expected.

Estimated Total Program Cost: $2,367.6 million
Research and development: $1,641.2 million
Procurement: $726.4 million
Quantity: 20

Next Major Program Event: System development start, April 2013

Program Office Comments: In commenting on a draft of this assessment, the B-2 program office provided technical comments, which were incorporated as appropriate.

2279 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

BMDS: Aegis BMD Standard Missile-3 Block IIB

MDA's Aegis Ballistic Missile Defense (BMD) system is a sea- and land-based system being developed to defend against missiles of all ranges. It includes a radar, command and control systems, and Standard Missile-3 (SM-3) missiles. We reviewed the SM-3 Block IIB, which is planned to provide U.S. homeland defense through early intercept capability against some long-range ballistic missiles and regional defense against intermediate-range ballistic missiles. The SM-3 Block IIB is planned to be fielded in the 2020 time frame as part of the European Phased Adaptive Approach.

Source: Missile Defense Agency.

Current Status

The SM-3 Block IIB program entered technology development in July 2011 and awarded three contracts to conduct trade studies, define missile configurations, and produce development plans. One contractor will be selected for system development in 2013. The SM-3 Block IIB program is developing advance seeker and other technologies that cut across the SM-3's variants through a technology risk-reduction program.

According to a tentative schedule, the SM-3 Block IIB program plans to enter system development prior to holding a preliminary design review, raising the possibility of cost and schedule growth. The program is conducting a series of reviews to receive engineering insight into each contractor's design. While these reviews will provide important knowledge, we have reported that before starting system development, programs should hold key engineering reviews, culminating in the preliminary design review, to ensure that the proposed design can meet defined, feasible requirements within cost, schedule, and other system constraints. Beyond the crosscutting technologies the program is developing, it is taking steps to develop technology maturation plans that will include demonstrating technologies in a relevant environment using a representative model or prototype before the SM-3 Block IIB enters system development. The three contractors' plans are expected to outline the level of investment required to demonstrate this degree of technology maturity by 2014. Program officials have not yet defined the specific critical technologies for the SM-3 Block IIB, which could hamper these efforts. Unlike most major defense acquisition programs, MDA programs are not required to demonstrate technologies in a relevant environment prior to system development, so decision makers will have to hold the program accountable for ensuring the technologies mature as intended.

Estimated Total Program Cost (fiscal years 2012 to 2016, research and development): $1,673.0 million

Next Major Program Event: System development start, fiscal year 2014

Program Office Comments: In commenting on a draft of this assessment, MDA noted the SM-3 Block IIB's primary mission is early intercept of long-range ballistic missiles. One system development contract will be competitively awarded in fiscal year 2014. MDA has identified key missile technologies and made investments to reduce development risks. Prior to system development, there will be a government-only system requirements review. MDA also provided technical comments, which were incorporated as appropriate.

2280 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Combat Rescue Helicopter (CRH)

The Air Force's Combat Rescue Helicopter (CRH) program, formerly called HH-60 Recapitalization, is an effort to replace aging HH-60G Pave Hawk helicopters. The CRH's primary mission is to recover personnel from hostile or denied territory; it will also conduct humanitarian, civil search and rescue, disaster relief, and noncombatant evacuation missions. The program is the second effort to replace the HH-60G. The first, the Combat Search and Rescue Replacement Vehicle (CSAR-X), was cancelled because of cost concerns in 2009.

Source: U.S. Air Force.

Current Status

The CRH program expects to receive its materiel development decision by February 2012. The Air Force expects that the CRH will be an existing production helicopter with modifications that utilize existing mature technologies or subsystems requiring limited integration. As a result, the program's acquisition strategy calls for it to bypass technology development and enter the acquisition process at system development. The Secretary of the Air Force endorsed the program's acquisition approach in April 2011, but requested that the program refine its fiscal year 2013 cost and schedule estimates before moving forward. The program office made these refinements through market research and requests for information from industry. The program plans to issue a request for proposal and award a contract in 2013. According to the program office, the CRH will undergo DOD's new pre–system development review to determine whether the program's plans are executable, affordable, and reflect sound business practices before a request for proposal is issued.

In order to address a critical shortfall in HH-60G aircraft, the Air Force has also initiated an Operational Loss Replacement (OLR) program, which will modify Army UH-60Ms to provide additional HH-60 aircraft to meet current fleet size requirements. These HH-60 aircraft are expected to remain in operation until the CRHs are fully deployed. CRHs are expected to begin being deployed on or before 2018.

Estimated Total Program Cost (fiscal years 2012 to 2016): $2,128.3 million
Quantity: 112

Next Major Program Event: Materiel development decision, February 2012

Program Office Comments: In commenting on a draft of this assessment, the Air Force generally concurred with our assessment, but stressed the fact that the CRH and OLR programs are two separate acquisition efforts. The OLR is designed to maintain the capability of the current HH-60 fleet, while the CRH is designed to provide improved capability in the future. The Air Force also provided technical comments, which were incorporated as appropriate.

2281 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Common Infrared Countermeasure (CIRCM)

The Army's CIRCM, the next generation of the Advanced Threat Infrared Countermeasures (ATIRCM), will be used with the Common Missile Warning System (CMWS) and a countermeasure dispenser capable of employing expendables, such as flares and chaff, to defend aircraft from infrared-guided missiles. The CIRCM program will develop a laser-based countermeasure system for rotary-wing, tilt-rotor, and small fixed-wing aircraft across DOD. CIRCM is one of three subprograms that make up the ATIRCM/CMWS major defense acquisition program.

Source: U.S. Army.

Current Status

The CIRCM program entered technology development in January 2012 after earlier prototyping efforts did not produce a system mature enough to enter system development. The CIRCM subprogram began in 2009 when the Under Secretary of Defense for Acquisition, Technology and Logistics supported the Army's decision to restructure the ATIRCM/CMWS program. At that time, the Under Secretary determined that aircraft survivability equipment development needed better coordination of service efforts, more emphasis on competitive prototyping, and a greater focus on reducing ownership cost by increasing reliability. In June 2009, the Army received approval to award five contracts to provide prototype systems for testing. After testing the five prototypes, the Army concluded that the systems were not mature enough for entry into system development. The Army subsequently decided that the program should proceed with a technology development phase that will include additional prototyping efforts to further mature CIRCM technologies. The Army released the final request for proposal for the CIRCM technology development phase in February 2011 and proposals were due in May 2011. The Army awarded two contracts in January 2012. According to the Army, there are several risks for CIRCM in technology development, including immature technologies that could result in an inability to meet a key performance requirement and the weight of the system, which may be too heavy for small aircraft. The Army has mitigation plans in place to address these issues and plans to update its risk assessment once the winning contractors and their designs are known.

Estimated Total Program Cost: $3,448.9 million
Research and development: $754.8 million
Procurement: $2,694.1 million
Quantities: 1,076

Next Major Program Event: Technology development contract award, January 2012

Program Office Comments: In commenting on a draft of this assessment, the Army provided technical comments, which were incorporated as appropriate.

2282 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Common Vertical Lift Support Platform (CVLSP)

The Air Force's Common Vertical Lift Support Platform (CVLSP) is expected to replace the current fleet of UH-1N helicopters with 93 vertical lift aircraft that can provide improved speed, range, and survivability. CVLSP will support a variety of missions including nuclear security operations and mass passenger transport in the National Capital Region. Initial operational capability for the CVLSP aircraft is planned for fiscal year 2015.

Source: U.S. Air Force.

Current Status

In May 2010, the CVLSP program received its materiel development decision and, in August 2011, the Air Force approved the program's acquisition strategy. The Air Force plans to use full and open competition to identify, select, and procure an in-production, nondevelopmental, commercial- or government-off-the-shelf aircraft. As a result, the program plans to bypass system development and enter the acquisition process at production. Air Force market research found that multiple aircraft currently in production could meet CVLSP requirements and industry has the capacity to produce the aircraft at the desired rates. Program officials noted that because all of the candidate aircraft are in production and operational use, their associated subsystems and critical technologies are considered mature. As a result, the Air Force expects that the program's total research and development cost will only be $33.5 million, primarily to support testing.

At the time the Air Force approved the CVLSP acquisition strategy, the program office was planning to issue a draft request for proposal in September 2011 and a final one in January 2012, award a contract in December 2012, and hold a low-rate initial production decision review in June 2013. However, the release of the draft request for proposal has been delayed indefinitely as the Air Force reviews all of its programs and budget in light of the fiscal constraints currently facing the entire federal government. According to program officials, senior Air Force leadership will decide if and when to release the draft request for proposal. The effect of the delay on the program's plans depends on the eventual timing of the release and the direction from Air Force leadership that accompanies it.

Estimated Total Program Cost: $3,626.3 million
Research and development: $33.5 million
Procurement: $3,561.1 million
Quantities: 93

Next Major Program Event: Release of the draft request for proposal, TBD

Program Office Comments: The program office concurred with this assessment.

2283 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

DDG 51 Destroyer

The DDG 51 destroyer is a multimission surface ship designed to operate against air, surface, and subsurface threats. After an approximate 4-year production break, the Navy restarted Flight IIA production and plans to buy 10 ships between fiscal years 2010 and 2015. The Navy will begin buying a new version—Flight III—in fiscal year 2016. Flight III is expected to include the Air and Missile Defense Radar (AMDR)—which is being developed under a separate Navy program—and have an increased focus on ballistic and cruise missile defense.

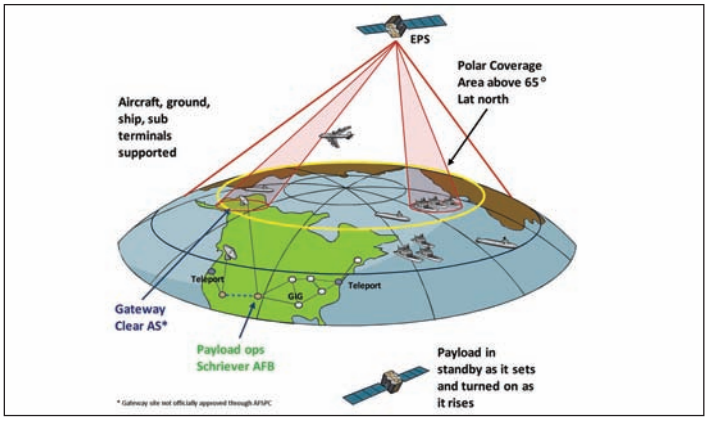
Source: U.S. Navy.

Current Status

In 2011, the Navy awarded contracts for three Flight IIA ships with an option for a fourth ship to restart DDG 51 production. Construction of the first ship—DDG 113—began in July 2011. The production break resulted in fewer industrial base issues than the Navy expected; however, the amount budgeted for the first three restart ships is $1.8 billion (in constant fiscal year 2012 dollars) more than for the last three ships built. According to the Navy, the ships will not have significant design changes, but will carry an upgraded Aegis combat system, which is currently being developed. The upgrade is expected to enable limited simultaneous, integrated ballistic and cruise missile defense and is the most complex Aegis upgrade ever undertaken. Recent delays in the effort have increased the likelihood the program may still be resolving software defects when it is installed on DDG 113. Further, test plans show that the Navy will certify the upgrade is mission-ready without validating with simultaneous live-fire tests that it can perform its new integrated air and missile defense mission.

The Navy is still determining which technologies will be included on Flight III. To date, the Navy has identified AMDR as the only major technology upgrade for Flight III, and technical studies indicate that few of the technologies developed for the DDG 1000 program are likely to be included on it. AMDR may add significant design and construction risk to Flight III and limit future upgrades based on its size and power and cooling requirements. Program officials stated that a decision has not been made about AMDR's size, which will affect the ship's missile defense capabilities and how much its power and cooling capabilities need to be increased. Further, the Navy has not determined the level of oversight that the Flight III program will have or at which—if any—milestone the program will enter the DOD acquisition cycle.

Estimated Total Program Cost (fiscal years 2010 to 2016): $17,755.6 million
Research and development: $797.6 million
Procurement: $16,958.0 million
Quantity: 11



Next Major Program Event: AMDR system development start, October 2012

Program Office Comments: In commenting on a draft of this assessment, the Navy stated that the last three ships built were part of a multiyear procurement, while the DDG 113 was a sole-source procurement and the next three ships were awarded through a limited competition, which may affect a comparison of their costs. Further, these ships, unlike earlier ones, include ballistic missile defense capability. The Navy also commented that the Aegis upgrade will be sufficiently mature to support DDG 113 shipbuilding milestones. The Navy also provided technical comments, which were incorporated as appropriate.

2284 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Enhanced Polar System (EPS)

The Air Force's Enhanced Polar System will provide next-generation protected extremely high frequency (EHF) satellite communications in the polar region. It will replace the current Interim Polar System and serve as a polar adjunct to the Advanced EHF system. EPS consists of two EHF payloads hosted on classified satellites, a gateway to connect modified Navy Multiband Terminals to other communication systems, and a control and planning segment.

Source: LinQuest Corporation.

Current Status

The EPS program's entry into system development has been delayed by over 3 years, although the payload has moved forward with development activities to keep it on track with the scheduled launch of its classified host satellites. EPS was initiated in 2006 to fill the gap left by the cancellation of the Advanced Polar System. In 2007, the Under Secretary of Defense for Acquisition, Technology and Logistics directed the program to proceed to system development in order to synchronize the program's payload schedule with the host satellite production timeline. Payload development proceeded in 2008, but the program's entry into system development has been delayed. According to the program office, the latest delays have occurred because funding constraints required the program to reduce the capabilities of the control and planning segment and gateway and amend the EPS acquisition strategy. Once the revised acquisition strategy is approved, the program plans to award a development contract for the control and planning segment that would lead to a preliminary design review in the first quarter of fiscal year 2013 and a system development decision at the end of fiscal year 2013.

There is a risk that the payload will be on orbit before the control and planning segment is available. The payload, which consists of about 20 separate units such as processors and antennas, has been in development for several years and all of its critical technologies are mature. As each payload unit is flight qualified, they are delivered to the host for integration into the satellites, which are expected to be on-orbit in fiscal years 2015 and 2017. Program officials acknowledged that it will be a challenge to develop and build the control and planning segment, needed for the system to be fully functional, by the time the payloads reach orbit.

Estimated Total Program Cost: $1,530.0 million
Research and development: $1,468.3 million
Procurement: $61.7 million
Quantity: 2 payloads

Next Major Program Event: System development decision for control and planning segment and gateway, fourth quarter fiscal year 2013

Program Office Comments: The EPS program office provided technical comments, where were incorporated as appropriate.

2285 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Expeditionary Fighting Vehicle (EFV)

The Marine Corps' EFV was being developed to transport troops from ships offshore to inland locales at higher speeds and from longer distances than the Assault Amphibious Vehicle 7A1 (AAV 7A1), which it was supposed to replace. It was to have two variants—a troop carrier for 17 combat-equipped Marines and 3 crew members and a command vehicle to manage combat operations. In January 2011, the Secretary of Defense announced the cancellation of the EFV due to technology problems, development delays, and cost increases.

Source: U.S. Marine Corps.

Current Status

The EFV program has been cancelled and an official reported that the EFV contract will end in September 2012. Shutdown activities, which will cost about $200 million, are ongoing and will include harvesting technologies and conducting habitability, firepower, water speed, durability, and mine blast testing on EFV vehicles.

Despite the EFV's cancellation, the Marine Corps has determined that it still needs an amphibious assault vehicle with greater capabilities than the legacy AAV 7A1 and is conducting an analysis of alternatives to explore options for replacing that vehicle. In September 2011, DOD's Office of Cost Assessment and Program Evaluation issued guidance directing that this analysis include five options: the cancelled EFV (about $18 million per unit), a new amphibious vehicle, a new land-mission focused vehicle which will need to be transported from ship to the shore via another watercraft, upgrades to the legacy AAVs to address identified gaps in the vehicle's survivability, and upgrades to the legacy AAVs to address other capability gaps such as water and land mobility, networking, and lethality. The Marine Corps also noted that the analysis will consider relaxing the EFV's requirements to make the new solution more affordable. For example, the analysis assumes a reduction in the ship-to-shore launch distance from 25 nautical miles, which was required of the EFV, to a range of 12 to 25 nautical miles. A shorter launch distance would place Navy amphibious transport ships at greater risk to shore-based threats. The analysis of alternatives is expected to be complete before the end of fiscal year 2012.

Estimated Total Program Cost (through fiscal year 2011): $3,704.9 million

Next Major Program Event: EFV contract expiration, September 2012

Program Office Comments: The Marine Corps was provided a draft of this assessment and did not offer any comments.

2286 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

F-22 Modernization Increment 3.2B

The Air Force's F-22A Raptor is the only operational fifth-generation air-to-air and air-to-ground fighter/attack aircraft. This aircraft integrates stealth; supercruise; and advanced avionics, maneuverability, and weapons in one platform. The Air Force established the F-22A modernization and improvement program in 2003 to add enhanced air-to-ground, information warfare, reconnaissance, and other capabilities and improve the reliability and maintainability of the aircraft. The Air Force is upgrading the F-22A fleet in four increments.

Source: U.S. Air Force.

Current Status

The first F-22A modernization increment has been fielded. Operational testing for the second increment was delayed between March and September 2011 because of the stand-down of the entire F-22 fleet after a fatal crash, test range unavailability, and a technical issue relating to ground support equipment. Increment 3.2A—the third increment—began developing software for electronic protection, combat identification, and Link 16 communication upgrades in November 2011, with fielding planned to begin in 2014. Program officials reported in December 2011 that increment 3.2A was slightly ahead of its current schedule.

The fourth program increment, increment 3.2B, is expected to begin system development as a separate major defense acquisition program in fiscal year 2013. This increment plans to field AIM-9X and AIM-120D missiles and upgrade electronic protection, targeting capabilities, and communication capabilities by 2017. The 3.2B increment will benefit from investments that have already been made in the modernization program, including requirements and risk-reduction analyses and the development of hardware needed to integrate new capabilities.

The Air Force identified three critical technologies for increment 3.2B. The two technologies that will be used to integrate the AIM-9X missile with the aircraft are in the early stages of development and have only been tested in a lab environment. The Air Force expects these technologies to be demonstrated in a relevant environment by the start of system development. The third technology, which is needed to improve the ability to locate ground targets, has already been demonstrated in a relevant environment.

Estimated Total Program Cost: $1,567.5 million
Research and development: $1,040.9 million
Procurement: $526.6 million
Quantity: 143
Note: The program cost is for increment 3.2B. The total cost estimate for all of F-22's modernization increments and improvements is $12.7 billion.

Next Major Program Event: System development start, December 2012

Program Office Comments: The Air Force provided technical comments, which were incorporated as appropriate.

2287 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Ground Combat Vehicle (GCV)

The Army's Ground Combat Vehicle (GCV) is the cornerstone of its combat vehicle modernization strategy. The first variant is intended to be the service's next infantry fighting vehicle, replacing a portion of the current Bradley fleet. The Army wants GCV to provide a full-spectrum capability to perform offensive, defensive, stability, and support operations; carry a 9-soldier squad; emphasize force protection; and be available within 7 years of beginning technology development.

Source: U.S. Army.

Current Status

In August 2011, the Under Secretary of Defense for Acquisition, Technology and Logistics approved the GCV program's entry into a 24-month technology development phase with the goals of reducing overall risk and achieving an affordable, feasible, and operationally effective preliminary design. During technology development, the Army plans to utilize a three-pronged approach that includes an updated analysis of alternatives; an assessment of selected nondevelopmental vehicles, such as an upgraded Bradley vehicle; and contractor efforts to build and demonstrate key subsystem prototypes. The Army awarded technology development contracts to two contractor teams. However, work could not begin until a bid protest from a third contractor team was resolved. The Army expects to have a preliminary design review within 18 months of beginning technology development and, at that point, according to an Army official, should be ready to determine whether GCV will be an entirely new vehicle or a modified existing vehicle.

In March 2011, we raised questions about the Army's strategy for the GCV program related to how urgently it is needed, the robustness of the analysis of alternatives, its cost and affordability, the plausibility of its schedule, and the maturity of the technologies to be used. DOD addressed some of these areas when it approved the program to enter technology development, but resolving others will be a major challenge for the Army. The Under Secretary of Defense for Acquisition, Technology and Logistics made approval of the program contingent upon the Army ensuring a procurement unit cost of $13 million per vehicle and a 7-year schedule for the first production vehicle to be delivered—both ambitious goals. The Army has encouraged contractors to use mature technologies in their designs, which we have found to be a key determinant to program success.

Estimated Total Program Cost: $31,589.9 million
Research and development: $6,789.7 million
Procurement: $24,800.2 million
Quantities: 30 (development), 1,874 (procurement)

Next Major Program Event: System development start, December 2013

Program Office Comments: The program office provided technical comments, which were incorporated as appropriate.

2288 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Joint Light Tactical Vehicle (JLTV)

The Army and Marine Corps' Joint Light Tactical Vehicle is a family of vehicles being developed to replace the High Mobility Multipurpose Wheeled Vehicle (HMMWV) for some missions. The JLTV is expected to provide better protection for passengers against current and future battlefield threats, increased payload capacity, and improved automotive performance over the up-armored HMMWV; it must also be transportable. Two- and four- seat variants are planned with multiple mission configurations.

Source: Department of Defense.

Current Status

On the basis of the knowledge gained in technology development, the Army and Marine Corps made changes to JLTV requirements. In October 2008, the Army awarded three technology development contracts with the goal of defining requirements, reducing risks, and shortening the length of system development. The contractors delivered prototype vehicles in May 2010 and testing was completed in June 2011. On the basis of the results, the Army and Marine Corps concluded that the original JLTV requirements were not achievable and its cost would be too high. For example, the JLTV could not meet requirements for both protection levels and transportability because of weight. The services have relaxed part of the requirement to transport the vehicle by helicopter at high altitude and at certain temperatures, which will permit a heavier vehicle to be transported. As a result of the requirements changes, the Army and Marine Corps will shift some missions intended for JLTV to the HMMWV.

The JLTV program has also made changes to its acquisition strategy. The Army and Marine Corps had planned to follow a traditional acquisition approach and enter system development in January 2012. The services now plan to use a tailored approach that includes awarding contracts to up to three vendors to build 20 vehicles, extensively testing those vehicles, and proceeding to production. Contract award is scheduled for June 2012. Contractors will have 12 months to build and deliver their prototypes, after which the government will spend 15 months testing them. A decision to begin production is planned for second quarter fiscal year 2015. DOD sees this approach as saving time and money; however, it forgoes the activities typically done early in system development that demonstrate the product's design is mature and will meet requirements. As a result, the Army and Marine Corps are at risk of discovering that the vehicles are still not mature late in the program.

Estimated Total Program Cost: TBD

Next Major Program Event: Contract award, June 2012

Program Office Comments: In commenting on a draft of this assessment, the program stated that as requirements were adjusted to reflect more achievable and cost-effective thresholds, system development could be shortened by leveraging existing designs. The program will focus the selection criteria on mature designs that manage the risks. Robust testing will allow sufficient opportunities for contractors to address issues throughout testing. The program also provided technical comments, which were incorporated as appropriate.

2289 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Joint Tactical Radio System (JTRS) Ground Mobile Radios (GMR)

DOD's JTRS program was developing software-defined radios intended to interoperate with selected radios and increase communications and networking capabilities. The JTRS GMR program was developing radios for ground vehicles and the software needed to operate them. The JTRS GMR contract also included the development of the wideband networking waveform. In October 2011, DOD terminated the JTRS GMR program. It plans to pursue an alternative strategy to meet ground vehicle networking and communications requirements.

Source: Department of Defense.

Current Status

In October 2011, the JTRS GMR program was terminated when the Acting Under Secretary of Defense for Acquisition, Technology and Logistics decided not to certify it to continue after a Nunn-McCurdy unit-cost breach of the critical threshold. The Under Secretary attributed the unit-cost growth to a reduction in quantity, an inadequate analysis of the program's affordability at its inception, a series of contractor and program execution issues, and the addition of new information-assurance requirements. The Under Secretary also noted that it was unlikely that the JTRS GMR program could meet its requirements in an affordable manner and may not meet some requirements at all. The radio had performed poorly during testing, prompting the test unit to conclude that its development should end and it should not be fielded. Finally, an assessment of alternative options found that a competitive market had emerged with the potential to deliver radios that meet the Army's capability needs at a reduced cost.

In order to meet networking requirements for ground vehicles, DOD plans to pursue a two-pronged approach. First, the current JTRS GMR contractor will continue development through March 2012 when the term of the contract ends, which will allow for completion of the JTRS GMR's National Security Agency information assurance certification, its operating environment software, and the wideband networking waveform. Second, DOD established a new program to test and evaluate low-cost, nondevelopmental radios with reduced size, weight, and power with a plan to field them in fiscal year 2014. In November 2011, the Navy Space and Naval Warfare Systems Command, on behalf of the JTRS Joint Program Executive Office, released a draft request for proposal for this new program to seek input from industry, with the expectation that a formal solicitation will be released in February 2012.

Estimated Total Program Cost (through fiscal year 2011): $1,832.3 million

Next Major Program Event: NA

Program Office Comments: The JTRS Joint Program Executive Office was provided a draft of this assessment and did not offer any comments.

Nett Warrior

The Army's Nett Warrior program is an integrated situational awareness system for use during combat operations. It was to consist of a radio furnished by the government and several contractor-developed items including a hands-free display, headset, and computer. According to program officials, the program is being restructured to deliver useable increments of capability sooner and for less money. The Army now plans to procure a commercially developed system that is considerably smaller and lighter.

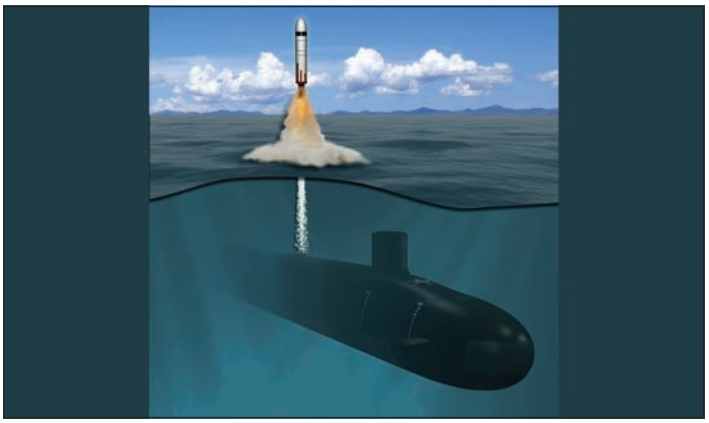
Source: U.S. Army.

Current Status

The Nett Warrior program is being restructured based on concerns about its affordability and performance in testing. The program was approved to enter technology development in February 2009 and planned to proceed directly to production in fiscal year 2011. The Army awarded cost-plus-fixed-fee contracts to three contractors for a suite of prototype equipment, which included a hands-free display, headset, computer, navigation equipment, antenna, and cables, that would eventually integrate with a government-furnished JTRS Rifleman radio. These prototypes underwent developmental testing and were evaluated in an October 2010 limited user test. Program officials indicated that a number of performance issues were revealed during testing and the size, weight, and power demands of the system resulted in it having little to no overall operational benefit. In September 2011, the Army decided to restructure the program, and program officials stated that a stop work order was issued for all three contractors.

Program officials further stated that the Army now plans to provide soldiers with commercially based, smart phone–type devices connected to a JTRS Rifleman radio. According to the Army, moving to a commercial solution will significantly reduce the cost and weight of the Nett Warrior capability. Before the restructuring, the program was projected to cost $1.936 billion to develop and acquire 74,197 sets of equipment. Program officials indicate that the new system is projected to reduce costs by as much as 60 percent and, as a result, the program is no longer considered a major defense acquisition. The new system was evaluated in the Army's semiannual network integration evaluation that concluded in November 2011. The Army plans to utilize the results from this test to inform a competitive procurement, which will then be followed by additional testing and the planned deployment of an incremental capability in fiscal year 2013.

Estimated Total Program Cost: TBD



Next Major Program Event: Production decision, March 2012

Program Office Comments: In commenting on a draft of this assessment, the program office acknowledged the requirement changes the program has experienced, which serve to emphasize the potential benefits provided by commercially developed equipment solutions. The program office also provided technical comments, which were incorporated as appropriate.

2291 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Ohio-Class Replacement (OR)

The Navy's *Ohio*-class Replacement (OR) will replace the current fleet of *Ohio*-class ballistic missile submarines (SSBN) as they begin to retire in 2027. The Navy began research and development in 2008, in order to avoid a gap in sea-based nuclear deterrence between the *Ohio*-class's retirement and the production of a replacement. The Navy is working with the United Kingdom to develop a common missile compartment for use on OR and the United Kingdom's replacement for the Vanguard SSBN. OR will initially carry the Trident II missile.

Source: © 2010 General Dynamics Electric Boat.

Current Status

The OR program began technology development in January 2011. Affordability has been an early focus of the program. Due to its high cost, Navy officials have stated the OR program could stress Navy shipbuilding budgets in the 2020 to 2030 time frame. Program officials stated that they are trying to reduce the average procurement unit cost from an estimated $5.6 billion to $4.9 billion (in fiscal year 2010 dollars). The program is considering procuring OR as part of a block buy with the *Virginia*-class submarine to reduce procurement costs by an estimated 13 percent, and is lining up its production schedule to match that program in case this option is pursued. The Navy also decided to use 16 87-inch diameter tubes per submarine, which, while fewer than the *Ohio*-class, is expected to reduce costs while meeting the anticipated future strategic requirement based on arms reduction trends. According to the program, a four-way competition is ongoing to develop prototype tubes and efficient manufacturing processes for outfitting these tubes into the hull, including the use of a "quad pack" configuration that could reduce cost and construction time.

According to Navy officials, they are currently defining requirements and conducting early design work for the program with Electric Boat as the design agent responsible for the overall ship design and Huntington Ingalls Industries as a subcontractor. For example, the Navy is planning to use a new X-stern aft control surface configuration for steering the submarine, pending successful testing. This design is expected to provide the desired maneuverability and increase maintainability. OR may also use electric propulsion, which would help improve the submarine's stealthiness because it uses fewer moving parts. Program officials said they plan to have the three-dimensional design complete prior to starting construction on the lead ship to minimize rework, delays, and the potential for cost growth.

Estimated Total Program Cost: $90,433.5 million
Research and development: $11,142.8 million
Procurement: $79,290.7 million
Quantity: 12

Next Major Program Event: Preliminary design review, March 2014

Program Office Comments: The Navy provided technical comments, which were incorporated as appropriate.

2292 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Patriot/Medium Extended Air Defense System (MEADS) Combined Aggregate Program (CAP) Fire Unit

The Army's Patriot/Medium Extended Air Defense System (MEADS) Combined Aggregate Program was a ground-mobile system intended to provide low- to medium-altitude air and missile defense to counter tactical ballistic missiles, cruise missiles, or other air-breathing threats. It included Patriot missile upgrades with a new battle management system, launchers, radars, and reloaders. MEADS is being codeveloped by the United States, Germany, and Italy.

Source: Lockheed Martin/MBDA/LFK (MEADS International).

Current Status

In February 2011, the Office of the Secretary of Defense proposed ending U.S. involvement in the MEADS program before development had been completed. In making its decision, DOD cited lingering concerns about the high degree of risk in the program and its affordability. DOD still plans to provide $803.7 million in funding through fiscal year 2013 for design and development activities, as required by the terms of its existing memorandum of understanding with its international partners.

Since MEADS development cannot be completed with the funding currently provided under the memorandum of understanding, the program office will instead work towards a demonstration of capabilities, which includes two planned flight tests. Much of the remaining development effort will be focused on the multifunction fire control radar, launcher, and battle management system. Program officials stated that launcher development is on track, but the battle management software is delayed and the multifunction radar still faces hardware challenges. Further delays in the development of these items could cause the program to reduce the number of planned flight tests to one. The program has stopped developing the system support vehicle, MEADS network radio, and reloader. It has also curtailed development of the surveillance radar, but plans to provide a low-cost prototype with 50 percent of the planned active electronics of the full radar design for the demonstration. Program officials stated that the surveillance radar is the most important item for the United States because it can potentially be leveraged for other systems. Program elements, such as the near-vertical launcher and a cooling technology for rotating phased-array radars, also might prove useful on other air and missile defense programs.

Estimated Total Program Cost (through fiscal year 2013): $3,280.4 million

Next Major Program Event: First flight test, November 2012

Program Office Comments: In commenting on a draft of this assessment, the Army stated that limited activities may continue into fiscal year 2014 and beyond. For example, international and U.S.-only contract closeout activities and data archiving may extend beyond fiscal year 2013. Additionally, the European partners may continue MEADS element development, which would require U.S. support through foreign military sales.

2293 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Presidential Helicopter (VXX)

The Navy's VXX program is intended to develop a presidential helicopter replacement fleet that will provide transportation for the President, Vice President, heads of state, and others as directed. The VXX fleet will replace the current fleet of VH-3D and VH-60N helicopters. The initial replacement effort, the VH-71, was terminated in June 2009 due to excessive cost growth and schedule delays, but the requirement to field a replacement remained. The Navy is also taking steps to extend the life of the current VH-3D/VH-60N fleet and streamline the VXX acquisition strategy.

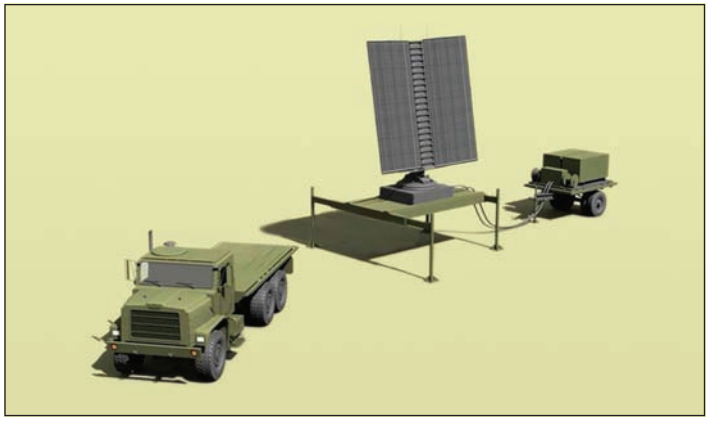
Source: U.S. Navy.

Current Status

In June 2010, the VXX program received its materiel development decision and began assessing alternatives to replace the existing VH-3D/VH-60N helicopter fleet. The Navy completed and provided to DOD the results of its analysis of alternatives in March 2011. DOD officials reviewed the results and determined that the Navy's analysis study did not find an acceptable—that is, cost-effective—solution. The Office of the Secretary of Defense (OSD) and the Navy subsequently decided to update the analysis of alternatives using an acquisition strategy that might result in a more timely and affordable program using additional guidance provided by OSD in December 2011. This strategy is based on leveraging mature technologies that will be developed outside of the VXX program before including them on VXX aircraft. DOD officials stated that the new analysis of alternatives will also include revised configurations that will satisfy a refined set of requirements. The program has been delayed until this analysis is completed.

As a result of the termination of the VH-71 and delay of the VXX effort, the legacy Presidential helicopter fleet will be upgraded and its service life will be extended. The upgrades will address many, but not all, of the capability gaps of the legacy fleet. The Navy plans to conduct a service life extension program (SLEP) on the legacy fleet that will extend their service life by 4,000 hours. The VH-3D and VH-60N will receive these modifications, including structural enhancements, during their routine overhaul cycles. The SLEP will allow the aircraft to operate until replacement aircraft are fielded, which the Navy wants to accomplish as quickly as possible as it has stated that the capability shortfalls of the current fleet cannot be otherwise overcome.

Estimated Total Program Cost: TBD



Next Major Program Event: Revised VXX analysis of alternatives, TBD

Program Office Comments: The program office concurred with the assessment and provided technical comments, which were incorporated as appropriate.

2294 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Three Dimensional Expeditionary Long Range Radar (3DELRR)

The Air Force's 3DELRR will be the long-range, ground-based sensor for detecting, identifying, tracking, and reporting aircraft and missiles for the Joint Forces Air Component Commander. It will provide real-time data and support a range of expeditionary operations in all types of weather and terrain. It is being acquired to replace the Air Force's AN/TPS-75 radar systems. The Marine Corps is considering 3DELRR as a potential replacement to the AN/TPS-59 to support the Marine Air-Ground Task Force Commander.

Source: U.S. Air Force.

Current Status

The 3DELRR program entered technology development in May 2009. The Air Force awarded two contracts for competing prototypes and plans to conduct a full and open competition and award a single cost-plus incentive fee contract for additional technology development activities. These activities include defining the preliminary system design, conducting a preliminary design review, producing a functioning system prototype for a capability demonstration, and other risk-reduction activities. The contract will also include options for system development, which is expected to begin in the first quarter of fiscal year 2014, and initial production. The program office reported that it has delayed the release of the request for proposal for this contract indefinitely due to its ongoing revision of the 3DELRR acquisition strategy. The revision is focused on the program's affordability and plans for competition.

The 3DELRR program is focused on reducing technical risk before beginning system development and has identified eight critical technologies. In April 2011, an independent review team reported that the program successfully demonstrated its critical technologies between both prototypes, though program officials noted the technologies still need to be integrated and demonstrated as a system. The program's technology development strategy calls for these technologies to be nearing maturity and demonstrated in a relevant environment at the start of system development. The program also expects to complete a preliminary design review prior to system development. Initial operational capability for the radar is targeted for approximately 2020.

Estimated Total Program Cost: $2,124.0 million
Research and development: $754.6 million
Procurement: $1,369.4 million (Air Force only)
Quantities: 35 (Air Force only)

Next Major Program Event: Contract award, TBD

Program Office Comments: The program office concurred with this assessment.

2295 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Unmanned Carrier-Launched Airborne Surveillance and Strike (UCLASS) System

The Navy's UCLASS is expected to enable a single aircraft carrier to conduct sustained operations including intelligence, surveillance, and reconnaissance (ISR), as well as targeting, strike, and bomb damage assessment. The system will address a gap in persistent sea-based ISR with precision strike capabilities. It includes upgrades to carrier infrastructure and systems, upgrades to existing command and control systems, and an unmanned aerial vehicle.

Source: U.S. Navy.

Current Status

The UCLASS program received its materiel development decision in July 2011. The program aims to achieve a limited initial capability in 2018 using existing capabilities that the Navy believes can be leveraged to support a UCLASS platform. The feasibility of this strategy will depend, in part, on the success of Navy's Unmanned Combat Air System Aircraft Carrier Demonstration (UCAS-D). The UCAS-D program's scope consists of design, development, integration, and demonstration of a carrier-suitable, low-observable, unmanned combat air system platform in support of a future acquisition program. UCAS-D will demonstrate carrier operations, including autonomous aerial refueling, as well as mature critical technologies needed to operate and integrate the aircraft with the ship. The analysis of alternatives for the UCLASS program, which was planned to be completed in January 2012, assumes that the UCAS-D program is successful in maturing technologies required to conduct launch, recovery, and carrier-controlled airspace operations and that the technologies can be applied to the UCLASS. Although the UCAS-D aircraft is not scheduled to demonstrate a carrier landing until 2013, F/A-18 flight test points from June 2011 have demonstrated the unmanned landing technology that will be incorporated into the UCLASS design. The program is considering cost and performance trade-offs such as endurance, payload, speed, sensors, and survivability to ensure the system is affordable and can provide limited initial capability by 2018. The analysis of alternatives will also likely address options for incrementally growing capabilities over time through the use of modular ISR and precision strike mission packages. Officials stated that it is critical that a request for proposal be released in fiscal year 2012 for the program to achieve a 2018 limited initial capability.

Estimated Total Program Cost: TBD
Research and development (fiscal years 2012 to 2016): $2,422.7 million
Quantity: TBD

Next Major Program Event: Technology development start, September 2012

Program Office Comments: In commenting on a draft of this assessment, the Navy stated that UCLASS system design is informed by UCAS-D activities and successful UCAS-D surrogate carrier tests have proven the technologies that inform the UCLASS carrier and system specifications. These specifications support the UCLASS request for proposal release in fiscal year 2012. The President's Budget for Fiscal Year 2013 adjusts the schedule and associated funding to provide an intial capability by 2020 instead of 2018. The Navy also provided technical comments, which were incorporated as appropriate.

2296 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Agency Comments and Our Evaluation

DOD provided written comments on a draft of this report. The comments are reprinted in appendix VI. We also received technical comments from DOD, which have been addressed in the report as appropriate.

In its comments, DOD stated it appreciates our efforts to develop improved methods and metrics but, while it does not disagree with the data used, still does not fully agree with those methods and metrics. In particular, DOD states that the aggregate cost growth measures in the report fail to adequately address when, why, and how cost growth occurred. Specifically, DOD stated that the report does not make obvious in the aggregate measures or discussion that the portfolio changes every year. In addition, DOD commented that the cost of programs often increase or decrease for reasons other than overly optimistic planning, faulty estimating, or poor execution, such as changing requirements, funding incremental upgrades, changing inventory goals, and adjustments to production rates.

We believe the report includes observations that directly address each of these areas. We report the aggregate cost growth for DOD's 2011 portfolio of major defense acquisition programs over the last year, the past 5 years, and since programs' first full estimates. Our assessment also makes a number of observations that seek to determine the reasons for that aggregate cost growth, including examining how much of the procurement cost growth in the past year was due to changes in quantities and identifying the link between development cost growth for programs in production and incremental upgrades to these systems. Finally, the report includes analysis of how the portfolio has changed over the past year, how it is likely to change in the next fiscal year, and how this may affect both the number of programs and cost of DOD's portfolio of major defense acquisition programs.

We are sending copies of this report to the Secretary of Defense; the Secretaries of the Army, Navy, and Air Force; the Director of the Office of Management and Budget; and interested congressional committees. In addition, the report will be made available at no charge on the GAO Web site at http://www.gao.gov.

Scope and Methodology

Analysis of the Cost Performance of DOD's Portfolio of Major Defense Acquisition Programs

This report contains observations on the cost and schedule performance of the Department of Defense's (DOD) fiscal year 2011 major defense acquisition program portfolio. To develop these observations, we obtained and analyzed data from Selected Acquisition Reports (SAR) and other information in the Defense Acquisition Management Information Retrieval (DAMIR) Purview system, referred to as DAMIR.[1] We refer to programs with SARs dated December 2010 as the 2011 portfolio. We converted cost information to fiscal year 2012 dollars using conversion factors from the DOD Comptroller's National Defense Budget Estimates for Fiscal Year 2012 (table 5-9). Data for the total planned investment of major defense acquisition programs were obtained from DAMIR, which we aggregated for all programs using fiscal year 2012 dollars. To calculate cost remaining to completion we used funding stream data obtained from DAMIR on the programs in the 2011 portfolio to determine what funds had been allocated in prior years for all activities and how much funding is required for the program to complete its acquisition. The Missile Defense Agency's (MDA) Ballistic Missile Defense System (BMDS) is excluded from our analysis of the 2011 portfolio.

We also collected and analyzed data on the composition of DOD's major defense acquisition program portfolio. To determine changes in that portfolio, we compared the programs that issued SARs in December 2010 with the list of programs that issued SARs in December 2009. To assess the cost effect of changes to the major defense acquisition portfolio, we calculated the estimated total acquisition cost for the six programs exiting the portfolio and for the four programs entering the portfolio. To project the number and cost of programs expected to be in the 2012 portfolio, we used data from the December 2010 and September 2011 SARs to identify the programs leaving the portfolio and their estimated cost. We used data from DOD's 2011 Major Defense Acquisition Program list, program offices, and DOD's fiscal year 2012 budget request to estimate the number and cost of programs expected to enter the 2012 portfolio.

To compare the cost of major defense acquisition programs over the past year, 5 years, and from first full estimates, we collected data from December 2010, December 2009, and December 2005 SARs; acquisition

[1]DAMIR Purview is an executive information system operated by the Office of the Under Secretary of Defense for Acquisition, Technology and Logistics / Acquisition Resources and Analysis.

2300 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

program baselines; and program offices. We retrieved data on research, development, test, and evaluation; procurement; and total acquisition cost estimates for the 96 major defense acquisition programs in the 2011 portfolio. We divided some SAR programs into smaller elements, because DOD reports performance data on them separately, resulting in a total of 99 programs and subelements. We analyzed the data to determine the change in research and development, procurement, and total acquisition costs from the first full estimate, generally development start, to the current estimate. For the programs that did not have a development estimate, we compared the current estimate to the production estimate. Also, for the shipbuilding programs that had a planning estimate, we compared the current estimate to the planning estimate. For programs that began as non–major defense acquisition programs, the first full estimate we used as a baseline may be different than the original baseline contained in DOD SARs. When comparable cost and schedule data were not available for programs, we excluded them from the analysis. To calculate cost growth incurred over the past year, from 2010 to 2011, we calculated the difference between the December 2009 and December 2010 SARs for programs older than 1 year. For programs less than a year old, we calculated the difference between December 2010 and first full estimates. We converted all dollar figures to fiscal year 2012 constant dollars. We took a similar approach for calculating cost growth incurred from 2006 to 2011. We also obtained schedule information and calculated the cycle time from program start to initial operational capability; delay in obtaining initial operational capability; and the delay in initial capability as a percentage of total cycle time. Finally, we extracted data on program acquisition unit cost to determine whether a program's buying power had increased or decreased.

To calculate the amount of procurement cost growth attributable to quantity changes, we isolated the change in procurement quantities and the prior average procurement unit cost for programs over the past year. For those programs with a change in procurement quantities, we calculated the amount attributable to quantity changes as the change in quantity multiplied by the average procurement unit cost for the program a year ago. The resulting dollar amount is considered a change due solely to shifts in the number of units procured and may overestimate the amount of change expected when quantities increase and underestimate the expected change when quantities decrease as it does not account for other effects of quantity changes on procurement such as gain or loss of learning in production that could result in changes to unit cost over time or the use or absence of economic orders of material. However, these

2301 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

changes are accounted for as part of the change in cost not due to quantities. An average procurement unit cost was not included in last year's SAR for the Littoral Combat Ship program. We calculated an average procurement unit cost for the program using the procurement quantities and funding up through fiscal year 2010 included in this year's SAR.

To evaluate program performance against high-risk criteria discussed by DOD, the Office of Management and Budget (OMB), and GAO, we calculated how many programs had less than a 2 percent increase in total acquisition cost over the past year, less than a 10 percent increase over the past 5 years, and less than a 15 percent increase from first full estimates using data from December 2010, December 2009, and December 2005 SARs; acquisition program baselines; and program offices. For programs that began as non–major defense acquisition programs, the first full estimate we used as a baseline may be different than the original baseline contained in DOD SARs. For programs with multiple subprograms presented in the SARs we calculated the net effect of the subprograms to reach an aggregate program result.

Through discussions with DOD officials responsible for the database and confirming selected data with program offices, we determined that the SAR data and the information retrieved from DAMIR were sufficiently reliable for our purposes.

Analysis of Selected DOD Programs Using Knowledge-Based Criteria

Our analysis of how well programs are adhering to a knowledge-based acquisition approach focuses on 37 major defense acquisition programs that are in development or the early stages of production.

To assess the knowledge attained by key decision points (system development start or detailed design contract award for shipbuilding programs, critical design review or fabrication start for shipbuilding programs, and production start), we collected data from program offices about their knowledge at each point. In particular, we focused on the eight programs that entered these key acquisition points in 2011 and evaluated their adherence to knowledge-based practices. We did not validate the data provided by the program offices, but reviewed the data and performed various checks to determine that they were reliable enough for our purposes. Where we discovered discrepancies, we clarified the data accordingly.

2302 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Programs in our assessment were in various stages of the acquisition cycle, and not all of the programs provided knowledge information for each point. Programs were not included in our assessments if relevant decision or knowledge data were not available. For each decision point, we summarized knowledge attainment for the number of programs with data that achieved that knowledge point. Our analysis of knowledge attained at each key point includes factors that we have previously identified as being key to a knowledge-based acquisition approach, including holding early systems engineering reviews, testing an integrated prototype prior to the design review, using a reliability growth curve, planning for manufacturing, and testing a production-representative prototype prior to making a production decision. Additional information on how we collected these data is found in the product knowledge assessment section of this appendix. See appendix IV for a list of these practices.

Analysis of Acquisition Reform Implementation

To determine how DOD has begun to implement acquisition reforms, we obtained and analyzed the revised DOD 5000.02 acquisition instruction, the Weapon Systems Acquisition Reform Act of 2009, and the September 14, 2010, Under Secretary of Defense for Acquisition, Technology and Logistics memorandum on better buying power as well as the subsequent memorandums clarifying and implementing that guidance.

We analyzed data from surveys received from the 37 active and 16 future major defense acquisition programs in our assessment to determine the extent to which programs were implementing requirements for holding systems engineering reviews; developing competitive prototypes; maturing critical technologies; considering trade-offs among cost, schedule, and performance objectives before development start; and establishing affordability targets and "should cost" analyses. We also collected information on whether these programs are planning to incorporate competition into their acquisition strategies.[2]

[2]The statutory requirement is that the acquisition strategy for each major defense acquisition program include measures to ensure competition, or the option of competition, throughout the life cycle of the program. Weapon Systems Acquisition Reform Act of 2009, Pub. L. No. 111-23, § 202. The survey question with respect to this requirement for major defense acquisition programs read "Does the program's acquisition strategy call for competition between Milestone B and the completion of production?" For future programs the question read "Does the program's technology development strategy or acquisition strategy call for competition between Milestone B and the completion of production?" When programs answered "no" to the question, we interpreted that answer to mean that the program is not planning to incorporate competition, or the option of competition, after development start into the acquisition strategy.

2303 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

To collect data from future major defense acquisition programs—including cost and schedule estimates, technology maturity, and planned implementation of acquisition reforms—we distributed an electronic survey to 22 programs planning to become major defense acquisition programs and enter system development or bypass system development and start production. Both the surveys for current and future major defense acquisition programs were sent by e-mail in an attached Microsoft Word form that respondents could return electronically. We received responses from August to October 2011. During the course of our review, we dropped six future programs from this analysis; four because of schedule changes that prevented them from entering technology development in 2011, one due to program cancellation, and one because the program did not respond fully to our data request. Therefore, our assessment of future major defense acquisition programs consists of 16 programs that will likely become major defense acquisition programs and are nearing system development start or proceeding directly to a production decision.

To ensure the reliability of the data collected through our surveys, we took a number of steps to reduce measurement error, nonresponse error, and respondent bias. These steps included conducting two pretests for the future major defense acquisition program survey and three pretests for the major defense acquisition program survey by phone prior to distribution to ensure that our questions were clear, unbiased, and consistently interpreted; reviewing responses to identify obvious errors or inconsistencies; conducting follow-up to clarify responses when needed; and verifying the accuracy of a sample of keypunched surveys.

To determine the amount DOD plans to invest in future major defense acquisition programs before entering system development or, for those planning to bypass system development, production, we collected budget data from the President's Budget for Fiscal Years 2007 through 2012 for each of the 16 future major defense acquisition programs we reviewed. For each program, we summed all planned funding from program start through, but not including, the fiscal year of the planned start of system development or production. We obtained the planned start date of system development from the survey we submitted to 16 future major defense acquisition programs or other program office documentation. For two programs that were planning to bypass system development, we used the planned date of production start. For the 92 current major defense acquisition programs that reported a system development or production start date in their December 2010 SAR, we used annual funding stream data from DAMIR to calculate the investment made in each program from

2304 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

program start through, but not including, the fiscal year of the start of system development or production start for programs that bypassed system development. We converted both sets of numbers to fiscal year 2012 constant dollars using conversion factors from the DOD Comptroller's National Defense Budget Estimates for Fiscal Year 2012 (table 5-9).

Individual Assessments of Weapon Programs

In total, this report presents individual assessments of 68 weapon programs. A table listing these programs is found in appendix VII. Out of these programs, 48 are captured in a two-page format discussing technology, design, and manufacturing knowledge obtained and other program issues. Thirty-seven of these 48 two-page assessments are of major defense acquisition programs, most of which are in development or early production; 5 assessments are of elements of MDA's BMDS; and 6 assessments are of programs that were projected to become major defense acquisition programs during or soon after our review. The remaining 20 programs are described in a one-page format that describes their current status. These programs include 14 future major defense acquisition programs, 2 major defense acquisition programs that are well into production, 1 element of MDA's BMDS, and 3 major defense acquisition programs that were recently terminated. Over the past several years, DOD has revised policies governing weapon system acquisitions and changed the terminology used for major acquisition events. To make DOD's acquisition terminology more consistent across the 68 program assessments, we standardized the terminology for key program events. For most individual programs in our assessment, "development start" refers to the initiation of an acquisition program as well as the start of engineering and manufacturing development. This coincides with DOD's milestone B. A few programs in our assessment have a separate "program start" date, which begins a pre–system development phase for program definition and risk-reduction activities. This "program start" date generally coincides with DOD's former terminology for milestone I or DOD's current milestone A. The "production decision" generally refers to the decision to enter the production and deployment phase, typically with low-rate initial production. The "initial capability" refers to the initial operational capability—sometimes called first unit equipped or required asset availability. For shipbuilding programs, the schedule of key program events in relation to acquisition milestones varies for each program. Our work on shipbuilding best practices has identified the detailed design contract award and the start of lead ship fabrication as the points in the acquisition process roughly equivalent to development start and design

2305 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

review for other programs. For MDA programs that do not follow the standard DOD acquisition model but instead develop systems' capabilities incrementally, we identify the key technology development efforts that lead to an initial capability.

For each program we assessed in a two-page format, we present cost, schedule, and quantity data at the program's first full estimate and an estimate from the latest SAR or the program office reflecting 2011 data where they were available. The first full estimate is generally the cost estimate established at milestone B—development start; however, for a few programs that did not have such an estimate, we used the estimate at milestone C—production start—instead. For shipbuilding programs, we used their planning estimates if those estimates were available. For systems for which a first full estimate was not available, we only present the latest available estimate of cost and quantities. For the other programs assessed in a one-page format, we present the latest available estimate of cost and quantity from the program office.

For each program we assessed, all cost information is presented in fiscal year 2012 dollars. We converted cost information to fiscal year 2012 dollars using conversion factors from the DOD Comptroller's National Defense Budget Estimates for Fiscal Year 2012 (table 5-9). We have depicted only the program's main elements of acquisition cost—research and development and procurement. However, the total program cost also includes military construction and acquisition-related operation and maintenance costs. Because of rounding and these additional costs, in some situations, total cost may not match the exact sum of the research and development and procurement costs. The program unit costs are calculated by dividing the total program cost by the total quantities planned. In some instances, the data were not applicable, and we annotate this by using the term "not applicable (NA)." The quantities listed refer to total quantities, including both procurement and development quantities.

The schedule assessment for each program is based on acquisition cycle time, defined as the number of months between program start and the achievement of initial operational capability or an equivalent fielding date. In some instances the data were not yet available, and we annotate this by using the term "to be determined (TBD)" or "NA."

The information presented on the "funding needed to complete" is from fiscal year 2012 through completion and, unless otherwise noted, draws

2306 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

on information from SARs or on data from the program office. In some instances, the data were not available, and we annotate this by the term "TBD" or "NA." The quantities listed refer only to procurement quantities. Satellite programs, in particular, produce a large percentage of their total operational units as development quantities, which are not included in the quantity figure.

The intent of these comparisons is to provide an aggregate, or overall, picture of a program's history. These assessments represent the sum of the federal government's actions on a program, not just those of the program manager and the contractor. DOD does a number of detailed analyses of changes that attempt to link specific changes with triggering events or causes. Our analysis does not attempt to make such detailed distinctions.

Product Knowledge Data on Individual Two-Page Assessments

In our past work examining weapon acquisition issues and best practices for product development, we have found that leading commercial firms pursue an acquisition approach that is anchored in knowledge, whereby high levels of product knowledge are demonstrated by critical points in the acquisition process. On the basis of this work, we have identified three key knowledge points during the acquisition cycle—system development start, critical design review, and production start—at which programs need to demonstrate critical levels of knowledge to proceed. To assess the product development knowledge of each program at these key points, we reviewed data-collection instruments and surveys submitted by programs; however, not every program had responses to each element of the data-collection instrument or survey. We also reviewed pertinent program documentation and discussed the information presented on the data-collection instrument and survey with program officials as necessary.

To assess a program's readiness to enter system development, we collected data on critical technologies and early design reviews. To assess technology maturity, we asked program officials to apply a tool, referred to as Technology Readiness Levels (TRL), for our analysis. The National Aeronautics and Space Administration originally developed TRLs, and the Army and Air Force science and technology research organizations use them to determine when technologies are ready to be handed off from science and technology managers to product developers. TRLs are measured on a scale from 1 to 9, beginning with paper studies of a technology's feasibility and culminating with a technology fully integrated into a completed product. See appendix V for TRL definitions. Our best-

2307 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

practices work has shown that a TRL 7—demonstration of a technology in a realistic environment—is the level of technology maturity that constitutes a low risk for starting a product development program.[3] For shipbuilding programs, we have recommended that this level of maturity be achieved by the contract award for detailed design.[4] In our assessment, the technologies that have reached TRL 7, a prototype demonstrated in a realistic environment, are referred to as mature or fully mature. Those technologies that have reached TRL 6, a prototype demonstrated in a relevant environment, are referred to as approaching or nearing maturity. Satellite technologies that have achieved TRL 6 are assessed as fully mature due to the difficulty of demonstrating maturity in a realistic environment—space. In addition, we asked program officials to provide the date of the preliminary design review. We compared this date to the system development start date.

In most cases, we did not validate the program offices' selection of critical technologies or the determination of the demonstrated level of maturity. We sought to clarify the TRLs in those cases where information existed that raised concerns. If we were to conduct a detailed review, we might adjust the critical technologies assessed, their readiness levels demonstrated, or both. It was not always possible to reconstruct the technological maturity of a weapon system at key decision points after the passage of many years. Where practicable, we compared technology assessments provided by the program office to assessments conducted by officials from the Office of the Assistant Secretary of Defense for Research and Engineering.

To assess design stability, we asked program officials to provide the percentage of design drawings completed or projected for completion by the design review, the production decision, and as of our current assessment.[5] In most cases, we did not verify or validate the percentage of engineering drawings provided by the program office. We clarified the

2308 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

percentage of drawings completed in those cases where information that raised concerns existed. Completed drawings were defined as the number of drawings released or deemed releasable to manufacturing that can be considered the "build to" drawings. For shipbuilding programs, we asked program officials to provide the percentage of the three-dimensional product model that had been completed by the start of lead ship fabrication, and as of our current assessment.[6] To gain greater insights into design stability, we also asked program officials to provide the date they planned to first integrate and test all key subsystems and components into a system-level integrated prototype. We compared this date to the date of the design review. We did not assess whether shipbuilding programs had completed integrated prototypes.

To assess production maturity, we asked program officials to identify the number of critical manufacturing processes and, where available, to quantify the extent of statistical control achieved for those processes.[7] In most cases, we did not verify or validate the information provided by the program office. We clarified the number of critical manufacturing processes and the percentage of statistical process control where information existed that raised concerns. We used a standard called the Process Capability Index, a process-performance measurement that quantifies how closely a process is running to its specification limits. The index can be translated into an expected product defect rate, and we have found it to be a best practice. We also used data provided by the program offices on their manufacturing readiness levels (MRL) for process capability and control, a subthread tracked as part of the manufacturing readiness assessment process recommended by DOD, to determine production maturity. We assessed programs as having mature manufacturing processes if they reported an MRL 9 for that subthread—meaning, that manufacturing processes are stable, adequately controlled, and capable. To gain further insights into production maturity, we asked program officials whether the program planned to demonstrate critical manufacturing processes on a pilot production line before beginning low-rate production. We also asked programs on what date they planned to begin system-level development testing of a fully configured, production-representative prototype in its intended environment. We compared this

date to the production start date. We did not assess production maturity for shipbuilding programs.

Although the knowledge points provide excellent indicators of potential risks, by themselves they do not cover all elements of risk that a program encounters during development, such as funding instability. Our detailed reviews on individual systems normally provide a more comprehensive assessment of risk elements.

We conducted this performance audit from August 2011 to March 2012, in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

Changes in DOD's 2011 Portfolio of Major Defense Acquisition Programs over Time

Table 6 shows the change in research and development cost, procurement cost, total acquisition cost, and average delay in delivering initial operational capability for the Department of Defense's (DOD) 2011 portfolio of major defense acquisition programs. The table presents changes that have occurred on these programs in the last year, the last 5 years, and since their first full cost and schedule estimates.

Table 6: Changes in DOD's 2011 Portfolio of Major Defense Acquisition Programs over Time

Fiscal year 2012 dollars in billions

	1 year comparison (2010 to 2011)	5 year comparison (2006 to 2011)	Since first full estimate (baseline to 2011)
Increase in total research and development cost	$14 billion 4 percent	$39 billion 14 percent	$113 billion 54 percent
Increase in total procurement cost	$61 billion 5 percent	$192 billion 19 percent	$321 billion 36 percent
Increase in total acquisition cost	$74 billion 5 percent	$233 billion 17 percent	$447 billion 40 percent
Average delay in delivering initial capabilities	1 month 2 percent	9 months 11 percent	23 months 32 percent

Source: GAO analysis of DOD data.

Notes: Data were obtained from DOD's Selected Acquisition Reports. In a few cases data were obtained directly from program offices. Not all programs had comparable cost and schedule data and these programs were excluded from the analysis where appropriate. Portfolio performance data do not include costs of developing Missile Defense Agency elements. Total acquisition cost includes research and development, procurement, acquisition operation and maintenance, and system-specific military construction costs.

Current and First Full Cost Estimates for DOD's 2011 Portfolio of Major Defense Acquisition Programs

Table 7 contains the current and first full total acquisition cost estimates (in fiscal year 2012 dollars) for each program or element in the Department of Defense's (DOD) 2011 major defense acquisition program portfolio. We excluded elements of the Missile Defense Agency's Ballistic Missile Defense System because comparable current and first full cost estimates were not available. For each program we show the percent change in total acquisition cost from the first full estimate, as well as over the past year and 5 years.

Table 7: Current Cost Estimates and First Full Cost Estimates for DOD's 2011 Portfolio of Major Defense Acquisition Programs

Fiscal year 2012 dollars in millions

Program	Current total acquisition cost	First full total acquisition cost	Change in total acquisition cost from first full estimate (percent)	Change in total acquisition cost within the past year (percent)	Change in total acquisition cost within the past 5 years (percent)
V-22 Joint Services Advanced Vertical Lift Aircraft (OSPREY)	57,211	40,099	42.7	0.5	5.2
Vertical Take-off and Landing Tactical Unmanned Aerial Vehicle (VTUAV)	2,615	2,615	0.0	4.3	0.0
Virginia Class Submarine (SSN 774)	83,746	60,449	38.5	0.4	-6.0
Warfighter Information Network-Tactical (WIN-T) Increment 2	6,053	3,708	63.2	25.7	63.2
Warfighter Information Network-Tactical (WIN-T) Increment 3	13,871	16,368	-15.3	0.8	-15.3
Warfighter Information Network-Tactical (WIN-T) Increment I	4,505	4,087	10.2	10.8	10.2
Wideband Global SATCOM (WGS)	3,674	1,194	207.8	1.7	67.8

Source: GAO analysis of DOD data.

Notes: Data were obtained from DOD's Selected Acquisition Reports, acquisition program baselines, and, in some cases, program offices. Percent change in total acquisition cost for the Littoral Combat Ship program is shown as "NA" because DOD reported incomplete baseline and cost data for the program through 2010.

Knowledge-Based Acquisition Practices

GAO's prior work on best product-development practices found that successful programs take steps to gather knowledge that confirms that their technologies are mature, their designs stable, and their production processes are in control. Successful product developers ensure a high level of knowledge is achieved at key junctures in development. We characterize these junctures as knowledge points. The Related GAO Products section of this report includes references to the body of work that helped us identify these practices and apply them as criteria in weapon system reviews. The following summarizes these knowledge points and associated key practices.

Knowledge Point 1: Technologies, time, funding, and other resources match customer needs. Decision to invest in product development
Demonstrate technologies to a high readiness level—Technology Readiness Level 7—to ensure technologies will work in an operational environment
Ensure that requirements for product increment are informed by preliminary design review using systems engineering process (such as prototyping of preliminary design)
Establish cost and schedule estimates for product on the basis of knowledge from preliminary design using systems engineering tools (such as prototyping of preliminary design)
Constrain development phase (5 to 6 years or less) for incremental development
Ensure development phase fully funded (programmed in anticipation of milestone)
Align program manager tenure to complete development phase
Contract strategy that separates system integration and system demonstration activities
Conduct independent cost estimate
Conduct independent program assessment
Conduct major milestone decision review for development start
Knowledge Point 2: Design is stable and performs as expected. Decision to start building and testing production-representative prototypes
Complete system critical design review
Complete 90 percent of engineering design drawing packages
Complete subsystem and system design reviews
Demonstrate with system-level integrated prototype that design meets requirements
Complete the failure modes and effects analysis
Identify key system characteristics
Identify critical manufacturing processes
Establish reliability targets and growth plan on the basis of demonstrated reliability rates of components and subsystems

2318 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

(Continued From Previous Page)
Conduct independent cost estimate
Conduct independent program assessment
Conduct major milestone decision review to enter system demonstration
Knowledge Point 3: Production meets cost, schedule, and quality targets. Decision to produce first units for customer
Demonstrate manufacturing processes
Build and test production-representative prototypes to demonstrate product in intended environment
Test production-representative prototypes to achieve reliability goal
Collect statistical process control data
Demonstrate that critical processes are capable and in statistical control
Conduct independent cost estimate
Conduct independent program assessment
Conduct major milestone decision review to begin production

Technology Readiness Levels

Technology Readiness Level		Description	Hardware/software	Demonstration environment
1.	Basic principles observed and reported	Lowest level of technology readiness. Scientific research begins to be translated into applied research and development. Examples might include paper studies of a technology's basic properties.	None (paper studies and analysis)	None
2.	Technology concept and/or application formulated	Invention begins. Once basic principles are observed, practical applications can be invented. The application is speculative and there is no proof or detailed analysis to support the assumption. Examples are still limited to paper studies.	None (paper studies and analysis)	None
3.	Analytical and experimental critical function and/or characteristic proof of concept	Active research and development is initiated. This includes analytical studies and laboratory studies to physically validate analytical predictions of separate elements of the technology. Examples include components that are not yet integrated or representative.	Analytical studies and demonstration of nonscale individual components (pieces of subsystem)	Lab
4.	Component and/or breadboard validation in laboratory environment	Basic technological components are integrated to establish that the pieces will work together. This is relatively "low fidelity" compared to the eventual system. Examples include integration of "ad hoc" hardware in a laboratory.	Low-fidelity breadboard. Integration of nonscale components to show pieces will work together. Not fully functional or form or fit but representative of technically feasible approach suitable for flight articles.	Lab
5.	Component and/or breadboard validation in relevant environment	Fidelity of breadboard technology increases significantly. The basic technological components are integrated with reasonably realistic supporting elements so that the technology can be tested in a simulated environment. Examples include "high-fidelity" laboratory integration of components.	High-fidelity breadboard. Functionally equivalent but not necessarily form and/or fit (size, weight, materials, etc). Should be approaching appropriate scale. May include integration of several components with reasonably realistic support elements/subsystems to demonstrate functionality.	Lab demonstrating functionality but not form and fit. May include flight demonstrating breadboard in surrogate aircraft. Technology ready for detailed design studies.

2320 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

(Continued From Previous Page)

Technology Readiness Level		Description	Hardware/software	Demonstration environment
6.	System/subsystem model or prototype demonstration in a relevant environment	Representative model or prototype system, which is well beyond the breadboard tested for TRL 5, is tested in a relevant environment. Represents a major step up in a technology's demonstrated readiness. Examples include testing a prototype in a high-fidelity laboratory environment or in simulated realistic environment.	Prototype. Should be very close to form, fit, and function. Probably includes the integration of many new components and realistic supporting elements/subsystems if needed to demonstrate full functionality of the subsystem.	High-fidelity lab demonstration or limited/restricted flight demonstration for a relevant environment. Integration of technology is well defined.
7.	System prototype demonstration in a realistic environment	Prototype near or at planned operational system. Represents a major step up from TRL 6, requiring the demonstration of an actual system prototype in a realistic environment, such as in an aircraft, a vehicle, or space. Examples include testing the prototype in a test bed aircraft.	Prototype. Should be form, fit, and function integrated with other key supporting elements/subsystems to demonstrate full functionality of subsystem.	Flight demonstration in representative realistic environment such as flying test bed or demonstrator aircraft. Technology is well substantiated with test data.
8.	Actual system completed and "flight qualified" through test and demonstration	Technology has been proven to work in its final form and under expected conditions. In almost all cases, this TRL represents the end of true system development. Examples include developmental test and evaluation of the system in its intended weapon system to determine if it meets design specifications.	Flight-qualified hardware	Developmental Test and Evaluation (DT&E) in the actual system application.
9.	Actual system "flight proven" through successful mission operations	Actual application of the technology in its final form and under mission conditions, such as those encountered in operational test and evaluation. In almost all cases, this is the end of the last "bug fixing" aspects of true system development. Examples include using the system under operational mission conditions.	Actual system in final form	Operational Test and Evaluation (OT&E) in operational mission conditions.

Comments from the Department of Defense

OFFICE OF THE UNDER SECRETARY OF DEFENSE
3000 DEFENSE PENTAGON
WASHINGTON, DC 20301-3000

ACQUISITION,
TECHNOLOGY
AND LOGISTICS

MAR 14 2012

Mr. Michael J. Sullivan
Director, Acquisition and Sourcing Management
U.S. Government Accountability Office
441 G Street, NW
Washington, DC 20548

Dear Mr. Sullivan:

This is the Department of Defense response to the GAO Draft Report, GAO-12-400SP, "DEFENSE ACQUISITIONS: Assessments of Selected Weapon Programs," dated February 15, 2012 (GAO Code 120990).

The Department notes that this is the 10th annual report on this topic, and we appreciate the positive working relationship we have built with GAO over time and your efforts to develop improved methods and metrics. As you are aware, we still do not fully agree with the GAO cost growth metrics, nor with how GAO measures adequate knowledge for programs to proceed through the acquisition process. We have been making serious strides in getting cost growth under control, and we appreciate that you acknowledge those efforts, including those to implement WSARA and the Better Buying Power initiatives in your report.

We do not disagree with the data used in preparation of your report, or that cost growth, as a simplistic metric, has occurred. What the aggregate measures in the report fail to adequately address are basic questions of when, why, and how it occurred. Nor does the report make obvious in the aggregate measures and discussion, that the portfolio changes every year and the cost of programs often increases or decreases for reasons other than overly optimistic planning, faulty estimating, or poor execution. These are the problems the Department is working aggressively to isolate and address. The Department believes that other "cost growth" sources contributing to the aggregate numbers in the report, such as reacting to changing requirements, funding block or incremental upgrades to fielded systems, changing inventory goals, and adjustments to production rates, need to be segregated from the sources of cost growth the Department is properly focused on. We appreciate your efforts toward this end.

2322 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The Department appreciates the opportunity to comment on the draft report. Please feel free to call me, at 703-614-5737, if you have any questions.

Sincerely,

Nancy L. Spruill

GAO's Mission

The Government Accountability Office, the audit, evaluation, and investigative arm of Congress, exists to support Congress in meeting its constitutional responsibilities and to help improve the performance and accountability of the federal government for the American people. GAO examines the use of public funds; evaluates federal programs and policies; and provides analyses, recommendations, and other assistance to help Congress make informed oversight, policy, and funding decisions. GAO's commitment to good government is reflected in its core values of accountability, integrity, and reliability.

Obtaining Copies of GAO Reports and Testimony

The fastest and easiest way to obtain copies of GAO documents at no cost is through GAO's Web site (www.gao.gov). Each weekday afternoon, GAO posts on its Web site newly released reports, testimony, and correspondence. To have GAO e mail you a list of newly posted products, go to www.gao.gov and select "E-mail Updates."

Order by Phone

The price of each GAO publication reflects GAO's actual cost of production and distribution and depends on the number of pages in the publication and whether the publication is printed in color or black and white. Pricing and ordering information is posted on GAO's Web site, http://www.gao.gov/ordering.htm.

Place orders by calling (202) 512-6000, toll free (866) 801-7077, or

TDD (202) 512-2537.

Orders may be paid for using American Express, Discover Card, MasterCard, Visa, check, or money order. Call for additional information.

13. SUPPLEMENTARY NOTES

14. ABSTRACT
Dugway Proving Ground (DPG), located in west-central Utah, is a U.S. Department of Defense (DoD) test site for chemical and biological defensive testing; it is also home to multiple breeding pairs of golden eagles (Aquila chrysaetos). The presence of an eagle nest has the potential to stop military testing and training due to potential nest disturbance. It is vital to DPG and similar DoD installations to fully understand the status of in-use eagle nests on military lands. Using Unmanned Aircraft Systems (UAS) and Small Unmanned Aircraft Systems (sUAS), it may be possible to obtain accurate status updates of eagle nests on DoD lands more efficiently than can be accomplished on foot. The DPG Team designed a blind study conducting weekly golden eagle nest surveys on DPG to compare the effectiveness of sUAS, UAS, and ground observers.

ACKNOWLEDGEMENTS

This project was made possible with the support from US Army Dugway Proving Ground, which served as the host installation and provided invaluable guidance and technical review. The US Army Rapid Integration and Acceptance Center who provided access to UAS when available and supported and coordinated sUAS flights. The US Army Threat System Management Office which provided technical sUAS and exemption to policy guidance. This project was also supported by HawkWatch International, who provided subject matter expertise on golden eagles.

ABSTRACT

INTRODUCTION AND OBJECTIVES

Dugway Proving Ground (DPG), located in west-central Utah, is a U.S. Department of Defense (DoD) test site for chemical and biological defensive testing; it is also home to multiple breeding pairs of golden eagles (*Aquila chrysaetos*). The presence of an eagle nest has the potential to stop military testing and training due to potential nest disturbance. It is vital to DPG and similar DoD installations to fully understand the status of in-use eagle nests on military lands. Using Unmanned Aircraft Systems (UAS) and Small Unmanned Aircraft Systems (sUAS), it may be possible to obtain accurate status updates of eagle nests on DoD lands more efficiently than can be accomplished on foot. The DPG Team designed a blind study conducting weekly golden eagle nest surveys on DPG to compare the effectiveness of sUAS, UAS, and ground observers.

TECHNOLOGY DESCRIPTION

The DPG Team conducted weekly golden eagle nest surveys on DPG during the 2019 and 2020 nesting seasons, using a blind study design, to compare the effectiveness of three "survey systems": 1) a ground-based human observer, 2) a commercially available small Unmanned Aircraft System *(sUAS; DJI Matrice M600 and E Mergent RC E900),* and 3) a military-grade UAS platform *(MQ-1C Gray Eagle).*

PERFORMANCE AND COST ASSESSMENT

No single platform was clearly superior across all seasons and periods of observation. During the 2019 season, the sUAS observation team proved the most efficient at locating in-use and unknown nests, but it was more expensive than the ground observer (annual operation cost of approx. $130k for the sUAS, versus $20k for the ground observer). The UAS team did not observe frequently enough to be directly compared but appeared to be most efficient observing well-known nests with lots of metadata to reference. UAS costs were not directly assessed, as they operate as part of a larger installation program. Results differed significantly during the 2020 season after the sUAS platform used in 2019 was prohibited from use under the FY19 National Defense Authorization Act (NDAA). In 2020, the sUAS team had trouble locating nests or identifying status due to the change in platform/payload and was not as efficient as the ground observer. The results indicate that the use of an sUAS is effective but may not yet be able to cost-effectively replace ground monitoring. For instances where the nests are too high or terrain too rugged, sUAS are especially effective. As the cost of the sUAS system is reduced and the policy surrounding flying sUAS in DoD airspace is streamlined, it may become cost-effective compared to on-the-ground monitoring.

IMPLEMENTATION ISSUES

A major implementation issue with the use of sUAS in DoD airspace involves obtaining an Airworthiness Release (AWR) and Exemption to Policy (ETP). Both approvals take time to develop, review, and obtain approval. Good metadata and a member of the team that has experience with eagle behavior and good knowledge of the territory is key to obtaining useful data. The UAS observation method was the most uncertain and it proved to be unreliable as a method of weekly nest observations due to scheduling and payload restrictions. If the nest location was well known, the UAS was by far the fastest and most efficient observation method. However, the nature of the platform's flight and approach patterns made detailed nest metadata critical to the success of the survey.

EXECUTIVE SUMMARY

INTRODUCTION

Dugway Proving Ground (DPG), located in remote west-central Utah, serves as a Major Range Test and Facility Base (MRTFB) test site for chemical and biological defensive testing, battlefield smokes, and obscurants. In addition, DPG is home to multiple breeding pairs of golden eagles, which are protected under the Bald and Golden Eagle Protection Act (BGEPA) and the Migratory Bird Treaty Act (MBTA). Due to these regulatory drivers, the presence of an eagle nest has the potential to restrict military testing and training if military activity causes nest disturbance. It is therefore vital to the function of DPG and similar DoD testing and training ranges to fully understand the location and status of in-use eagle nests or territories on military lands.

Current survey techniques of nesting golden eagles on DPG and active DoD training properties require long-distance viewing of each nest from the ground at least weekly, which is both time-consuming, costly, and may not always provide a definitive status of nest changes *(Weissensteiner and Poelstra 2015)* due to limited visibility from the ground. Using both military-grade and commercial Unmanned Aircraft Systems (UAS)/Small Unmanned Aircraft Systems (sUAS), it is possible to obtain highly accurate locations and status updates of in-use golden eagle nests on DoD lands, data that is critical to maintaining open testing and training ranges for as much time as possible in the eagle nesting season *(Chabot and Bird 2015, Hodgson et al. 2016, Junda et al. 2015, Weissensteiner and Poelstra 2015)*. The sUAS/UAS can be used to detect new nests in areas that are difficult to see or access from the ground, as well as count nestlings and track nesting milestones in a less time-invasive manner not previously possible *(Weissensteiner and Poelstra 2015)*. All of this can be accomplished with greatly reduced disturbance to the nesting pairs *(through reduced time in the area)*, crucial to the success of sensitive nesters such as the golden eagle *(Chabot and Bird 2015, Scobie and Hugenholtz 2016, Weissensteiner and Poelstra 2015)*.

OBJECTIVES

Select Engineering Services (SES), in coordination with DPG, the Rapid Integration and Acceptance Center (RIAC), Threat Systems Management Office (TSMO), and HawkWatch International (HWI), hereinafter referred to as the DPG Team, developed this technology demonstration to demonstrate the use of sUAS/UAS as a cost-effective way to monitor golden eagles on military installations. Currently it takes approximately 960 hours to conduct on-the-ground monitoring of eagle nests for approximately six months *(based upon actual numbers provided by DPG and SES experience).* The primary objective was to reduce the total hours required to monitor the nests and evaluate the cost-effectiveness of using sUAS/UAS over in-person ground based monitoring. Other objectives of the demonstration included the following:

- Efficiencies of scale to monitor more nests in less time for a lower cost
- Demonstrated the effectiveness of sUAS/UAS versus on-the-ground observation
- Improved quality of still photos and videos for further analysis
- Demonstrated use of sUAS/UAS as safe and low disturbance to the eagles
- Demonstrated use of sUAS/UAS to enable greater access to the nest and ability to collect more detailed data

2340 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Demonstrated use of sUAS/UAS as more efficient in finding nests in particular settings such as hidden/remote terrain

TECHNOLOGY DESCRIPTION

The DPG Team conducted weekly golden eagle nest surveys on DPG during the 2019 and 2020 nesting seasons to compare the effectiveness of three "survey systems": 1) a ground-based human observer, 2) a commercially available sUAS, and 3) one or more military-grade UAS platform(s). These nest surveys were conducted as a blind study; none of the three teams of observers encountered one another in the field. None exchanged information concerning the nest surveys, and none had any access to data generated by surveys conducted by any of the other teams.

sUAS/UAS Platform Descriptions

In the 2019 study season, a DJI Matrice sUAS platform was procured with an approved DoD software patch, through the Army Ground Aerial Target Control System (AGATCS), in partnership with the TSMO. DJI Zenmuse Z30 cameras were used as the operational payload, with 32x optical zoom allowing for long-range HD observations. This system was approved for use during the 2019 nesting season. However, in December 2019 the National Defense Authorization Act (NDAA) was signed which stated that DoD could not operate or enter into or renew a contract for the procurement of a covered unmanned aircraft system that is manufactured in a covered foreign country. Foreign country was defined as People's Republic of China. sUAS platforms by DoD programs except in the case of sUAS counter-defense testing. This language was strictly interpreted to prevent the use of the modified DJI Matrice that was used the previous year. This led the DPG Team to seek out another option. Through discussions with TMSO, an alternative sUAS was identified for use, the E Mergent RC E900 platform. The two E900s were integrated with Sony FCB-EV7520A camera payloads.

DPG is also home to the Rapid Integration and Acceptance Center (RIAC) which was established by the Project Manager Unmanned Aircraft Systems to create a single location where unmanned and manned aircraft could complete end-to-end testing and integration. DPG coordinated with RIAC to conduct monitoring flights when they were not conducting mission flights. RIAC identified a military UAS platform that would be most suitable for this type of flight plan: the MQ-1C Gray Eagle.

Survey Methods

The DPG Team conducted weekly golden eagle nest surveys on DPG during the 2019 and 2020 nesting seasons to compare the effectiveness of three "survey systems": 1) a ground-based human observer, 2) a commercially available small Unmanned Aircraft System, and 3) one or more military-grade UAS platform(s). The ground-observer was a single vehicle-based biologist; the sUAS system included three personnel *(commercial pilot, observer, and biologist for video monitoring)*; and the military UAS required three personnel *(military pilot, military camera operator, and civilian biologist for video monitoring)*. All three biologists associated with each survey approach had comparable familiarity with existing DPG eagle territories and previous eagle nest monitoring experience.

2341 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The DPG Team generated territory-specific data sheets that specify known nests within 11 known territories on DPG, nest survey order based on historic use patterns, and other detailed survey instructions. The UAS observation team conducted a separate territory and nest survey effort designed to test the platform's capabilities as a precision, on demand survey system for areas with little to no ground access. Two senior DPG environmental staff provided weekly oversight of data collected by all three survey systems and collated survey results to ascertain the weekly "benchmark" status of each territory, and to ensure survey protocols were properly followed. Camera data from a subset of nests were also used to provide retrospective verification and correction of weekly status.

Each annual survey was segmented into two time-periods: the "early season", defined as 10 February–14 April *(9–10 weeks)* and the "late season", defined as 15 April–30 June *(12 weeks)*. The primary goal of the early season surveys was to document "Occupied Territories" (pair of adults present), "In-Use Nests" (nest with eggs or young), and "Vacant Territories" (no in-use nests and no adult birds in territory), while the goal of late season surveys was to track In-Use Nest to "Success" *(at least one nestling surviving to 80% fledge age)* or "Failure" *(terms adapted from Steenhof et al. [2017]).* During the early season, all 11 territories were surveyed every two weeks *(e.g., 6 one week, five the next).* In contrast, late season surveys were restricted to In-Use Nests found during the early season surveys, plus any territories with unresolved status.

For ground and sUAS survey systems, independent teams attempted to survey each nest from outside an 800-m horizontal protective buffer *(as widely prescribed on public lands and suggested by Romin and Muck [2002]).* Biologists associated with each survey system recorded eagle response behavior *(i.e., any agitation or flushing observed while conducting nest surveys).*

Surveys conducted for each platform followed specific territory and nest survey protocols to ensure comparable methods were employed and to facilitate the capture of detailed time-keeping records associated with specific survey tasks. Biologists for each survey system recorded total daily "Survey Time", which began upon departure from English Village *(ground and sUAS)* or initiation of take-off from the DPG airfield (UAS) and continued until return to same location at the end of the survey effort. For each platform, "Territory Survey Time" was noted, starting when entering into a 2km buffer around known nests associated with each territory, and continuing until status was confirmed, and the survey was complete, or a 3-hr time limit was reached. Time spent within each territory involved in "Area Search" *(general scanning overall area for adult and nesting evidence),* "Nest Search" *(prescribed order survey of known nests),* and "Extended Search" *(searching for new or uncatalogued nests)* was also recorded. Surveyors used standardized terminology established in this document and photographic guides to age eagle nestlings *(Driscoll 2010, Hoechlin 1976).*

PERFORMANCE ASSESSMENT

Time to Early Season Status

The ground observer and the sUAS took roughly the same amount of time to determine early season territory occupancy each year, even with the change in sUAS platform in 2020. The UAS platform was rarely able to make definitive determinations within the given time allowed, and its data was subsequently not comparable to the other platforms. Most of the time required by both the sUAS and ground observer was taken by drive time between nests in a territory.

2342 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

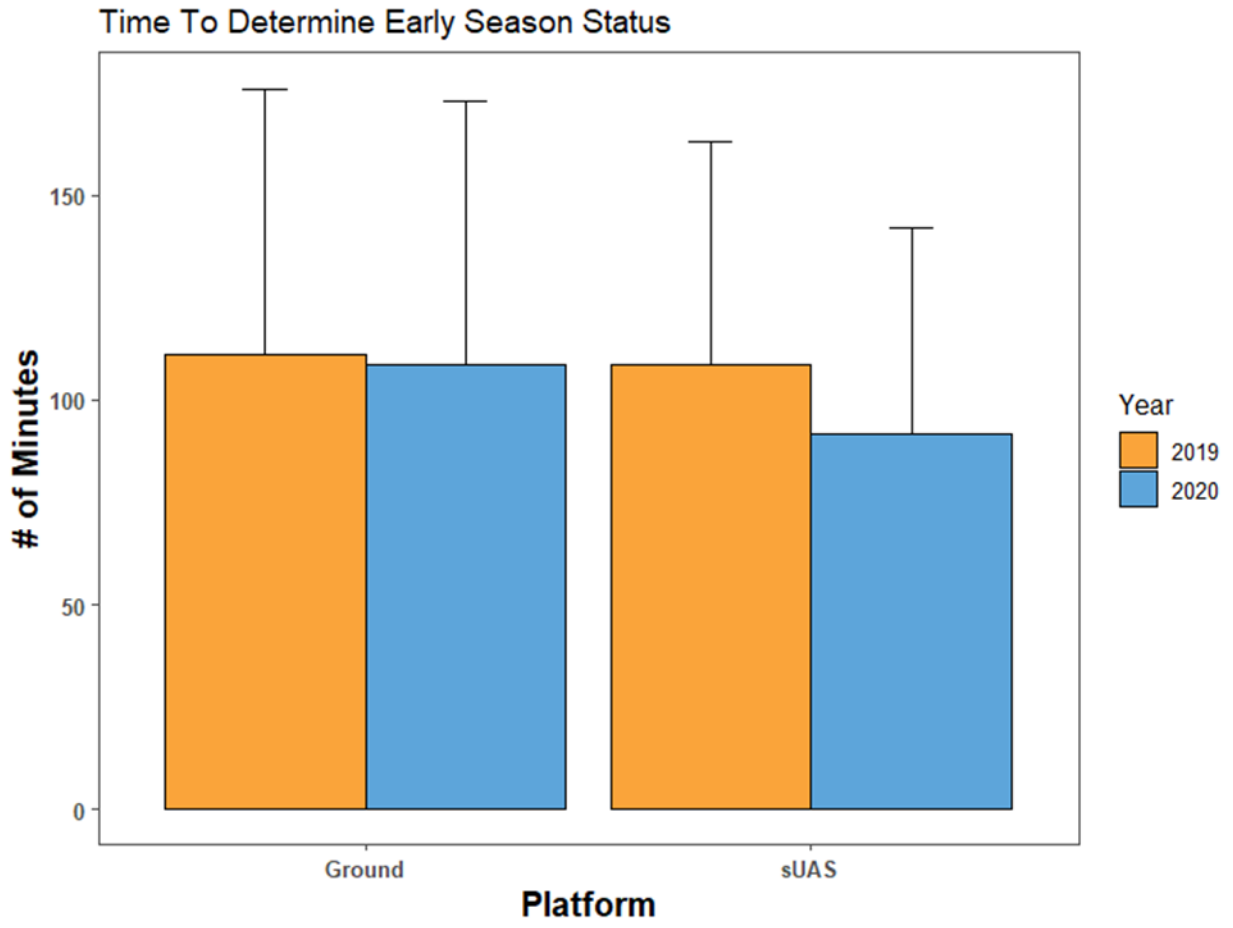

Figure ES-1. Chart Showing the Mean Time in Minutes (+SD) Each Platform Required to Determine the Early Season Occupancy of a Territory.

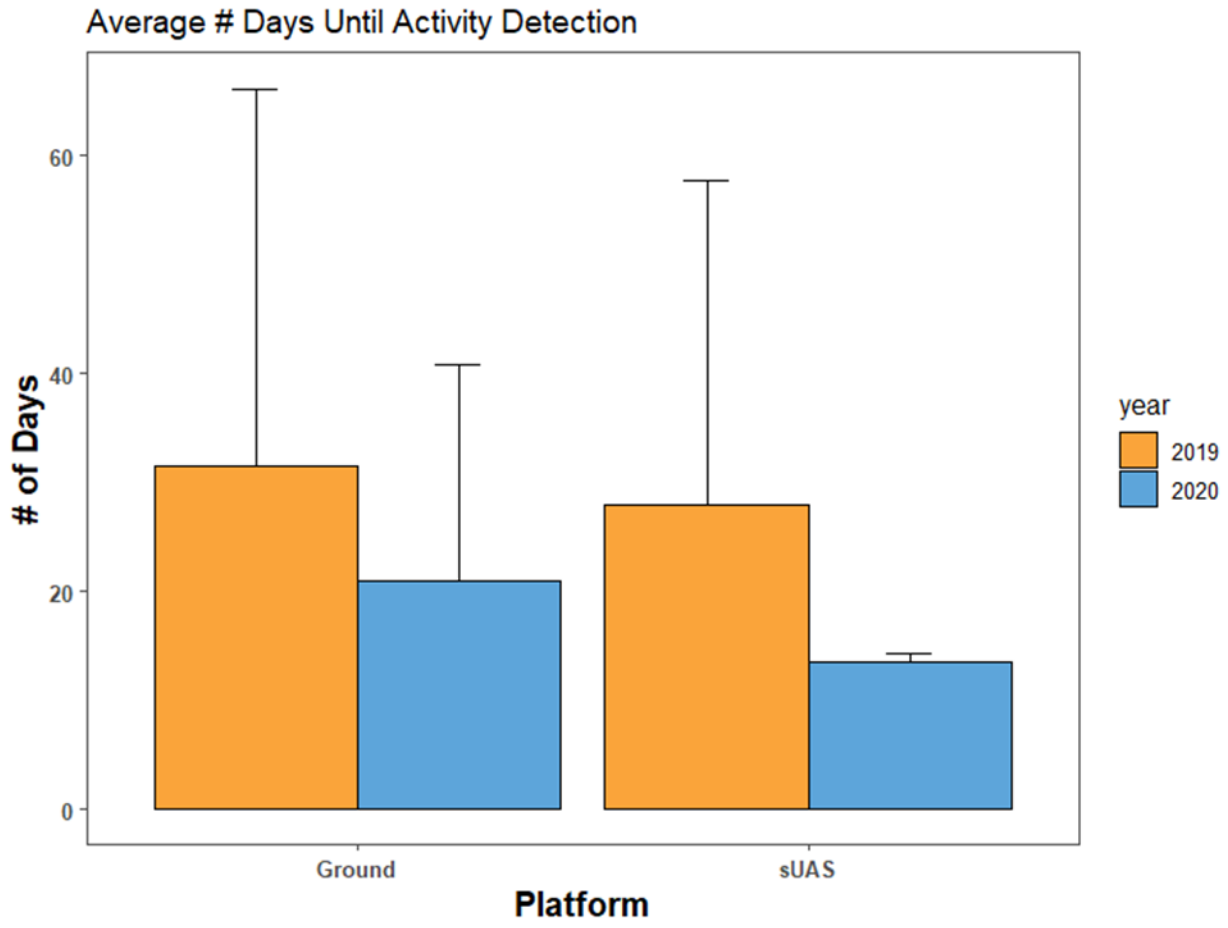
Date of In-Use Nest Identification

The sUAS platform was roughly equal with the ground observer at detecting in-use nests in 2019. The sUAS platform was able to survey almost every known nest in each assigned territory each week, making it more likely for the platform to detect an incubating eagle within a week of nesting initiation. The ground observer, on the other hand, was forced to rotate which nests were surveyed during each visit due to long hikes over rough terrain. The 2019 UAS was typically not able to identify nest activity due to the low resolution of its payload and the lack of precise nest metadata provided to its pilots and was not compared. In 2020 the sUAS was again roughly equal to the gound observer in nest detection time, despite the sUAS's drop in payload resolution. This indicates that the advantage of visiting more nests outweighed the disadvantage of poor payload resolution. In 2020, the UAS platform was forced to cease surveys before nests became in-use, removing it from this comparison.

2343 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



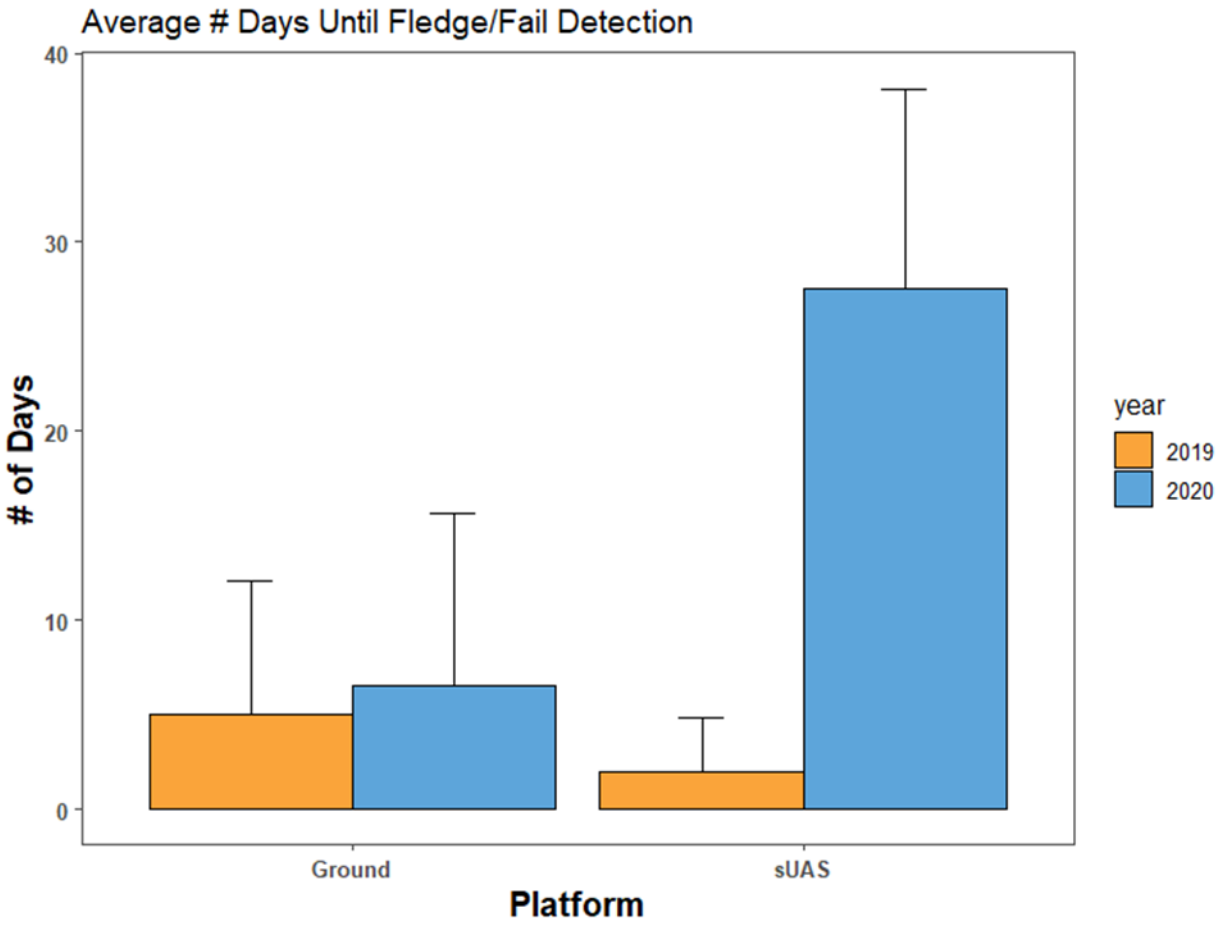


Figure ES-2. Chart Showing the Mean Number of Days (+SD) from Nest Initiation to Activity Detection by Each Platform.

Date of Nest Failure or Fledge Identification

In 2019, the ground observer and sUAS platforms very nearly tied for speed at detecting nest failure or fledge. Both had sufficient quality optics and visitation rates to detect the lack of chicks in a nest almost immediately. The UAS was not compared due to lack of data. By contrast, the ground observer was much faster to detect nest failure or fledge in 2020 than the sUAS. The sUAS's loss of payload resolution made it difficult for the platform to identify the presence or absence of small chicks in a nest. Again, the UAS was forced to cease surveys before nests became in-use, removing it from this comparison.

2344 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ES Figure ES-3. Chart Showing the Mean Number of Days (+SD) from Nest Failure or Fledge to Detection by Each Platform.

Time to Nest Status Update

These models illustrate the differences in nest observation efficiency both between platforms and between years. In 2019, the sUAS displayed a clear efficiency advantage over the ground observer, requiring much less observation time to make a nest status determination, especially in the early nesting season. This is because of the sUAS's ability to view directly into a nest bowl, eliminating the need to wait for a possible incubating eagle to stand or stretch in order to come into view from the ground. As the nesting season went on and chicks got larger, they were easier to see from below, decreasing the advantage of the sUAS. In 2020, the sUAS retained a small advantage over the ground observer, but the poor resolution of the payload meant that the platform had to observe each nest for much longer in order to determine if an object perceived to be in the nest was actually an eagle or if it was simply a pixilation artifact. In addition, the ground observer in 2020 took more time on average as the season went on, mostly due to the fact that one of the in-use nests was located in a high, partially obscured cliff cavity, preventing easy observation at any time.

2345 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

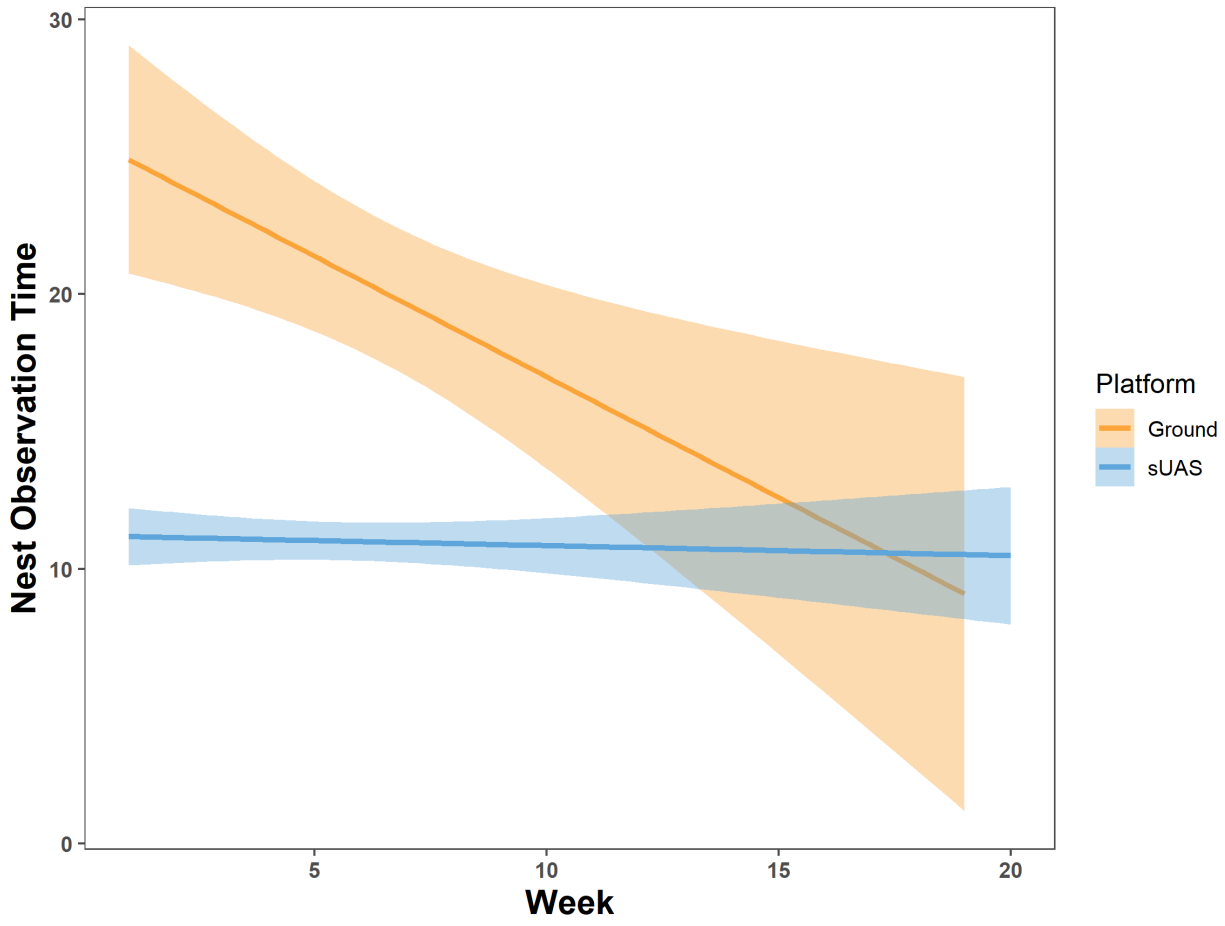

Figure ES-4. Comparison of the Efficiency of a Ground Observer in Minutes (± 95% Confidence Intervals) vs an sUAS at Determining Any Given Nest's Status During 2019.

The sUAS took vastly less time to determine status during early season, while the ground observer gained efficiency as unused nests were eliminated from the survey round.

2346 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

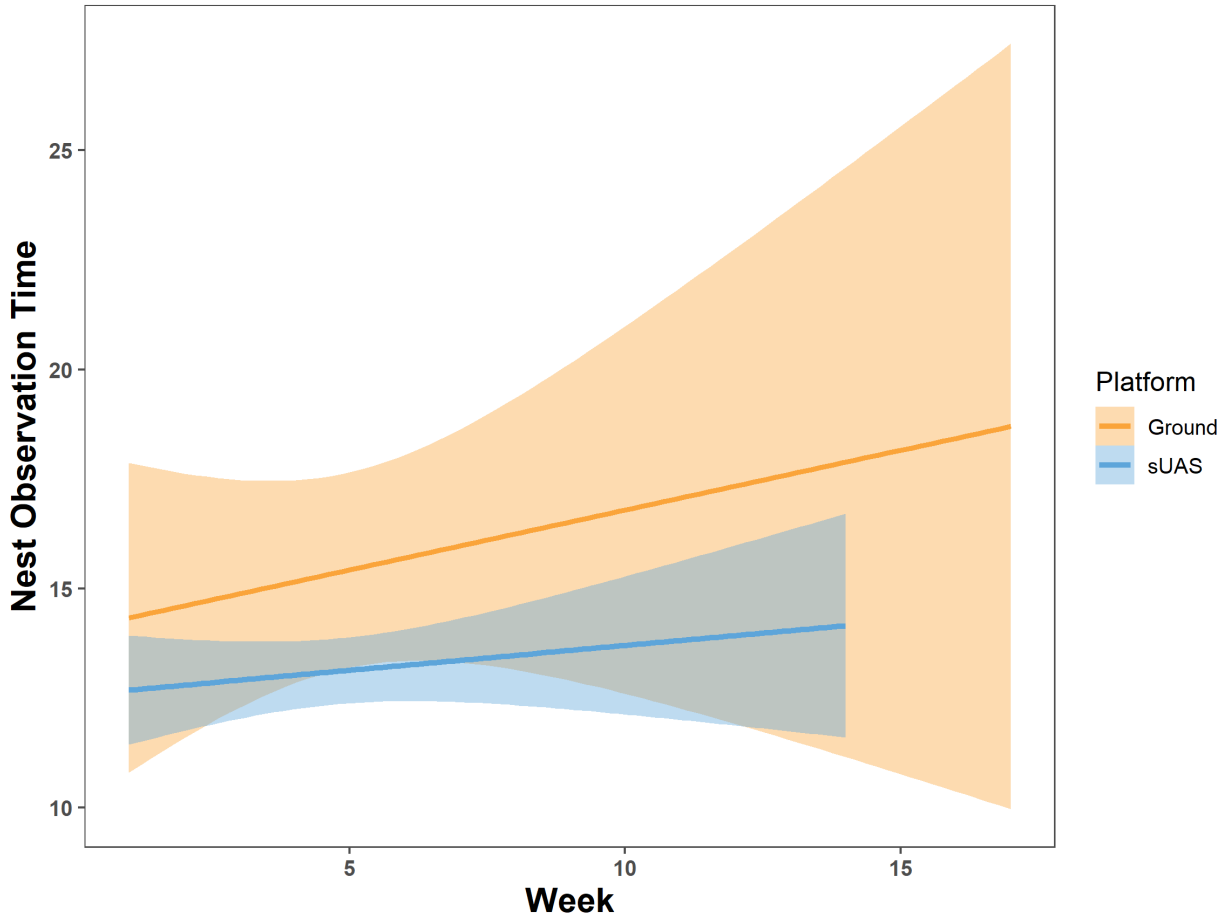

Figure ES-5. Comparison of the Efficiency of a Ground Observer in Minutes (± 95% Confidence Intervals) vs an sUAS at Determining Any Given Nest's Status During 2020.

The sUAS took less time to determine status on average, but the sUAS's efficiency advantage was much less pronounced than during 2019.

Hypothetical Mission Impact in Days

The hypothetical mission impact of nest area closures and openings is a measure of the precision of each platform in detecting nest status changes. Ideally, an in-use nest will be detected, and an area closure enacted immediately *(within one week or survey period)* upon the start of incubation, and the area opened again immediately upon the failure or fledge of the nest. This minimizes potential mission impacts of unnecessary range closures as well as protecting the nest against potential disturbance.

In 2019, both the ground observer and sUAS platform were slow to detect the activity of RN315, leaving it unprotected for several weeks, although the sUAS was one week quicker in detecting the nest's activity. In addition, the ground observer designated RN315 as fledged prematurely by one week. This resulted in the sUAS being cumulatively more precise in designating range closures in 2019 than the ground observer.

2347 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In 2020, the data is complicated by the fact that both the ground observer and the sUAS monitored nests that the other platform was not capable of reaching, leaving only one nest for direct comparison. The ground observer was slow to detect the activity of RN248A by several weeks but caught the fledge of the nest immediately. The rough terrain and lack of road access in RN248A's territory required the ground observer to ration which nests received a survey visit each week, which resulted in the in-use nest going undetected for several weeks. The sUAS detected the activity of RN029 immediately but was slow to confirm the failure of the nest by several weeks. The low resolution of the platform payload in 2020 made it much more difficult to identify the presence or absence of young chicks from the nest bowl than the presence or absence of an incubating adult. Both platforms were equally precise at determining the status of RN321.

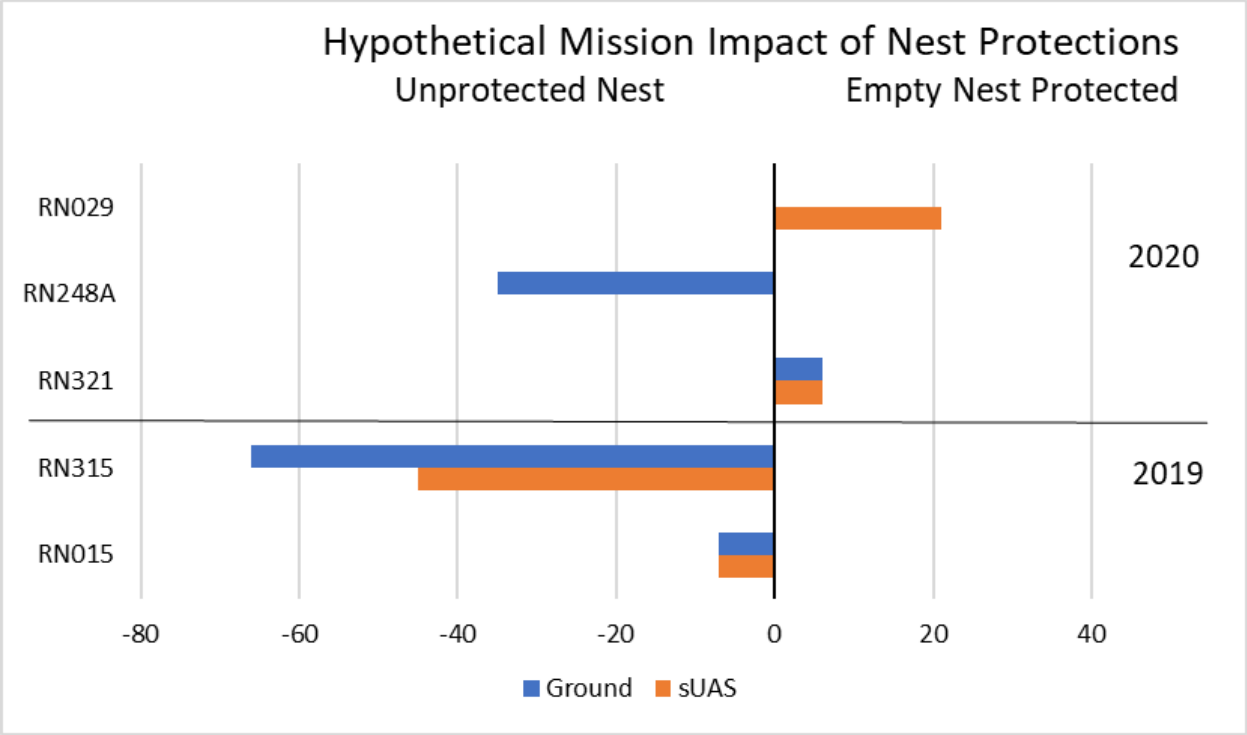

Figure ES-6. Chart Showing the Hypothetical Impact of Nest Area Closures/Openings by Platform and Year.

Quality of Photo/Video Documentation

The DPG Team conducted a qualitative evaluation of how well each platform was able to document nest status in both 2019 and 2020. In 2019, the sUAS platform delivered high resolution video and photo documentation of all nests viewed, as well as footage of the surrounding cliffs for the team to search for previously unknown nests. The photo/video documentation allowed the data managers to confirm nest status before putting range closures in place. By contrast, the UAS platform in 2019 was equipped with a low-resolution payload that hampered the observer's ability to identify nests with confidence. The UAS's thermal imaging capability did allow the observer to spot chicks in in-use nests, however. In 2020, the imaging capabilities of the sUAS and UAS platforms were reversed. The replacement sUAS platform had a downgraded payload resolution due to downlink limitations.

2348 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In addition, it did not have onboard data recording capabilities; the observation team had to record footage from the ground station, and as a result encountered significant issues with poor reception and signal corruption. These limitations resulted in the sUAS team requiring more time on site to determine nest status, and in many cases prevented the team from calling a certain nest status at all. On the other hand, the UAS platform received a significant upgrade to its payload systems, allowing for HD image recording. Unfortunately, the UAS team was forced to cease survey operations after only 2 weeks of monitoring due to the COVID-19 crisis, and the observation team was unable to obtain enough data to present a significant image comparison.

Figure ES-7. A Photo of RN315 As Taken by the sUAS Platform in 2019

(DJI Matrice 600 Pro with Zenmuse Z30 payload).

The photo shows an adult golden eagle sheltering a chick less than a week old.

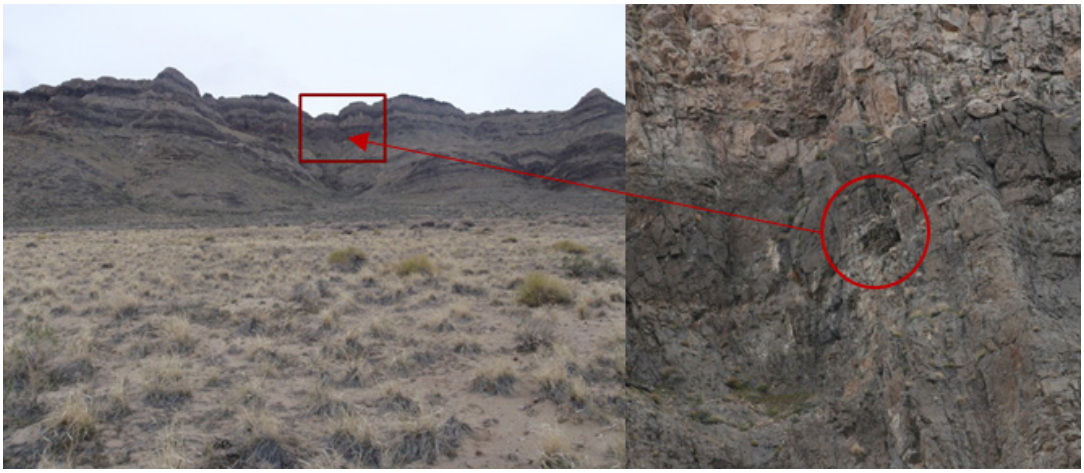

Figure ES-8. A Series of Two Photos Taken by a Ground Observer at Two Different Zoom Levels of RN046.

The first photo shows the distance the observer must view the nest from, as well as the height of the nest on the cliff face. The second photo shows how the ground observer must view the nest from below, even at high zoom.

2349 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

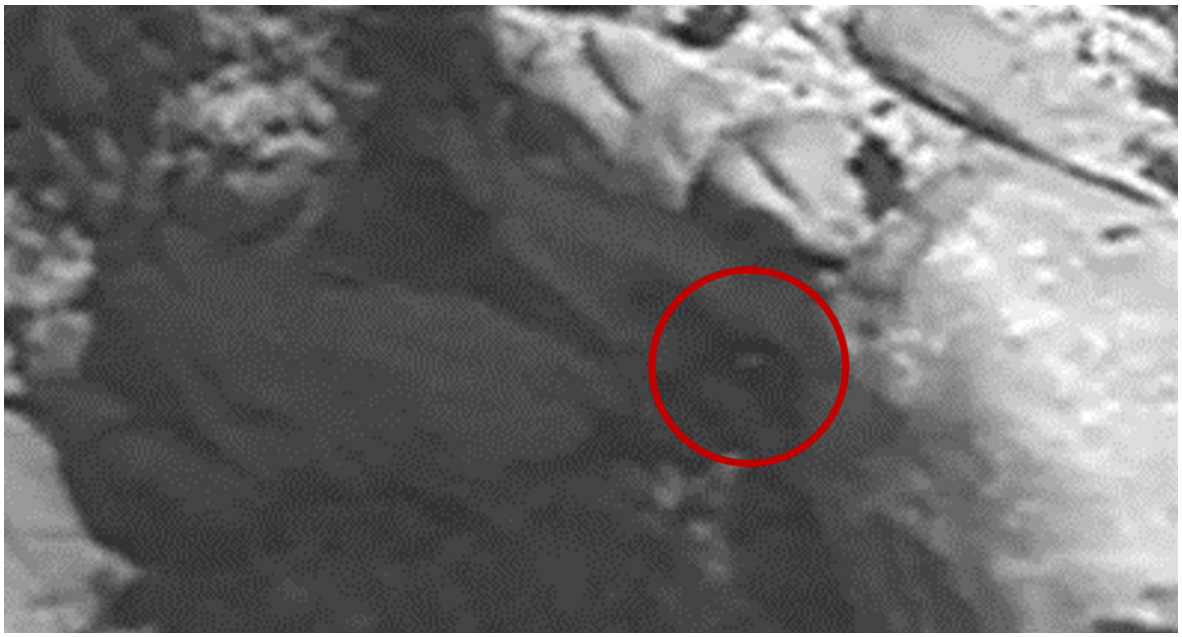

Figure ES-9. A Video Still Taken from the Footage of the UAS Observer Using Thermal Imaging in 2019, Showing RN315 with a Nearly 9-week-old Chick.

The chick is shown as a pale (warm) shape in the middle of a cool cliff face. This image shows the challenges the UAS observer faced with low resolution imagery, and how thermal imaging was able to partially compensate in the late nesting season.

Figure ES-10. A Video Still Taken from the Footage of the sUAS Observer in 2020 (E900 with Sony FCB-EV7520A), Viewing Nest RN248.

The photo shows the low resolution and video artifacts that inhibited the sUAS's ability to make accurate nest activity identifications in 2020.

2350 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Additional Metrics for Success

The results of the mixed-effect logistic regression models indicate that the ground observer and sUAS platform had essentially equal *(high)* accuracy in determining the status of any given nest in 2019. Both platforms were more than 85% likely to determine nest status accurately and confidently in the early season, growing to more than 95% accurate in the late season. This can be attributed to the experience and skill of the ground observer, as well as the ability of the sUAS platform to take high quality documentation photos and video for review. In 2020, the sUAS platform suffered greatly from the drop in payload resolution. It began strongly and was still confidently able to determine when nests were not in-use. However, it struggled to accurately identify when nests were in-use and to determine the difference between an incubating nest and a nest with chicks. The ground observer, on the other hand, displayed almost the same results as in 2019.

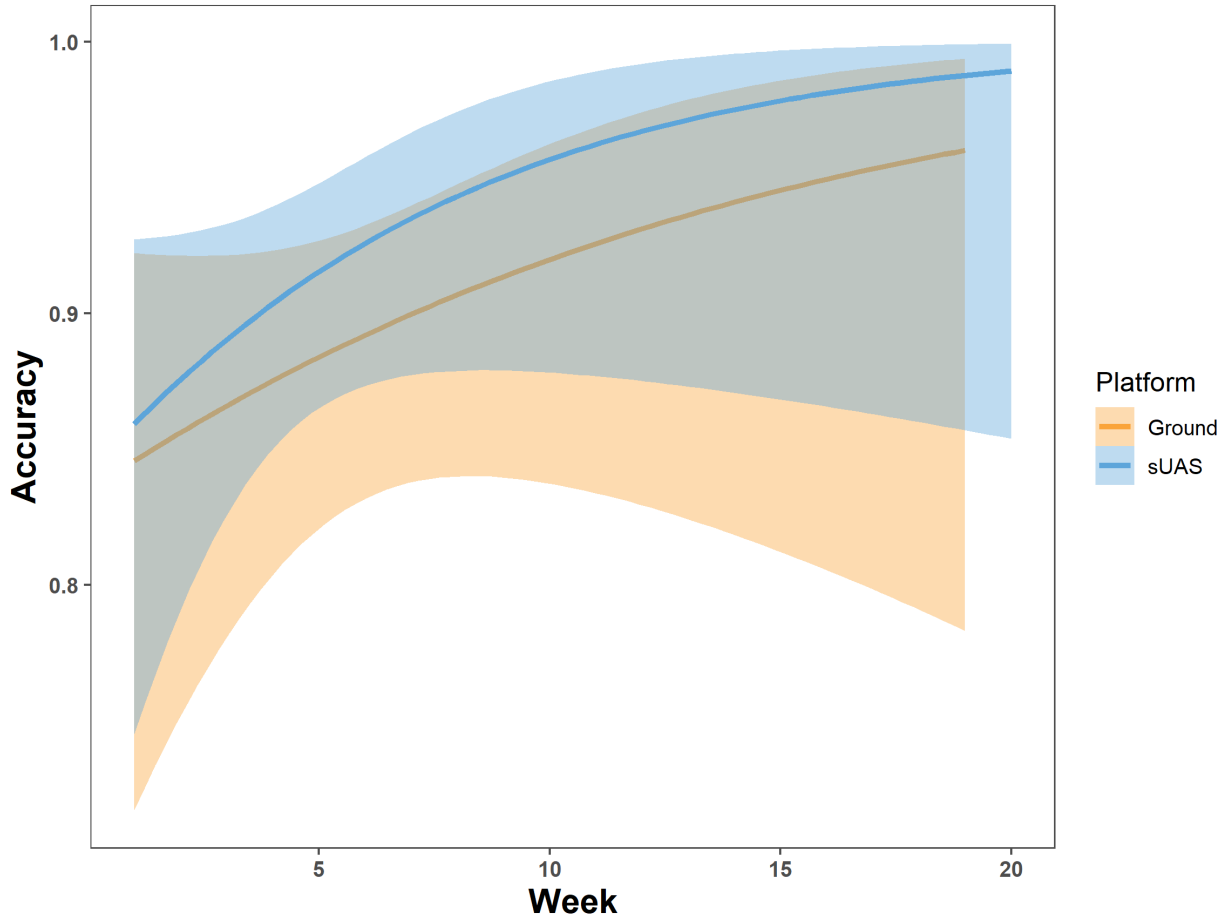

Figure ES-11. Comparison of the Accuracy of a Ground Observer (± 95% Confidence Intervals) vs an sUAS at Determining Any Given Nest's Status During 2019.

Both platforms gained accuracy as the season went on, remaining roughly equal in accuracy. Error margins represent 95% confidence intervals.

2351 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

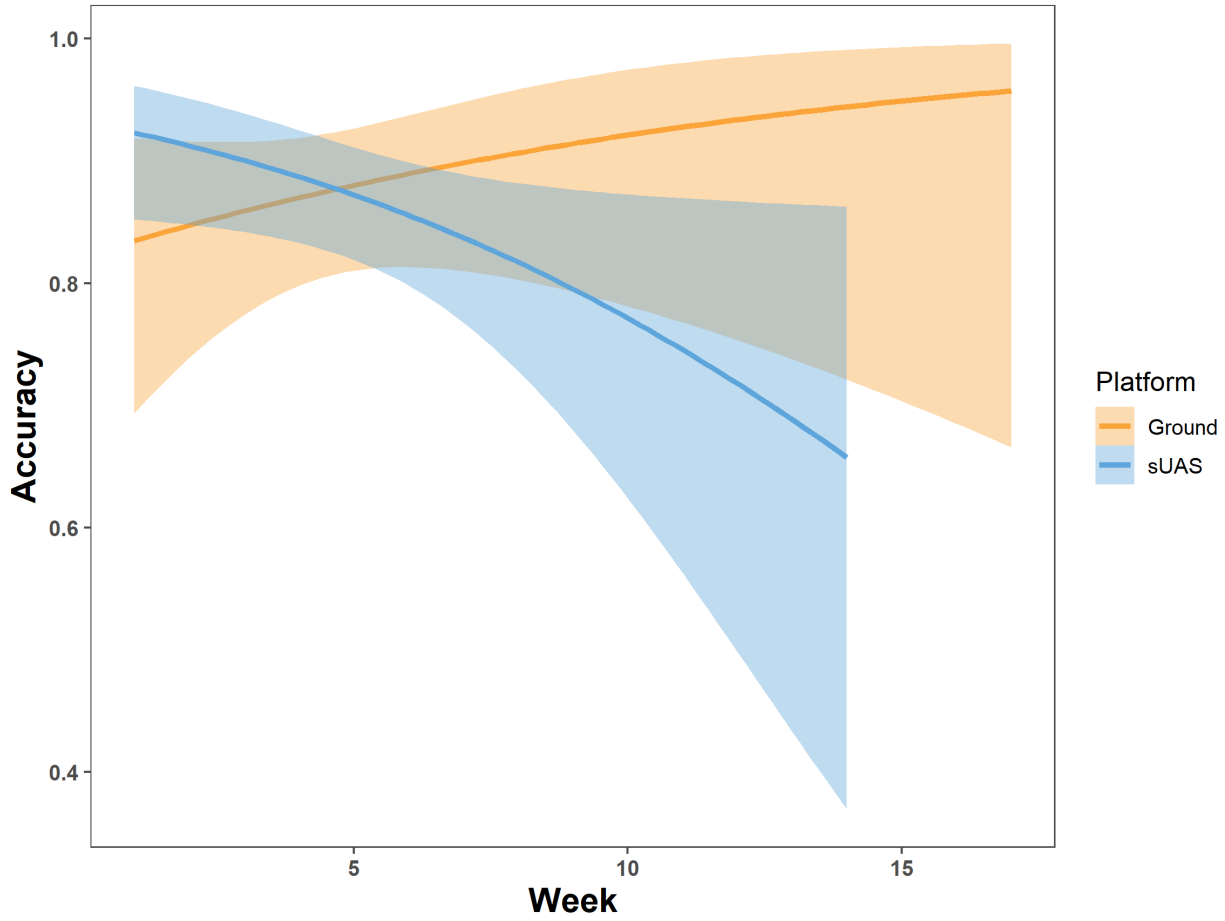

Figure ES-12. Comparison of the Accuracy of a Ground Observer (± 95% Confidence Intervals) vs an sUAS at Determining Any Given Nest's Status During 2020.

The ground observer gained accuracy during the season, mirroring 2019, while the sUAS lost accuracy. This represents the challenges of identifying an in-use nest's status with a low-resolution payload. Error margins represent 95% confidence intervals.

When determining which platform is most efficient and cost-effective, it is important to take total territory coverage into account, especially in the early nesting season when looking to identify in-use nests. The sUAS platform was able to survey approximately twice as many nests each week than the ground observer in both 2019 and 2020. This grants the sUAS more confidence in accurately calling the occupancy status of early season territories, as well as giving it an advantage in locating in-use nests promptly. This played out in 2019 as the sUAS located one in-use nest a full week before the ground observer. The ground observer had to rotate which nests to observe each week due to time pressure and the lengthy hikes needed to cover some territories. By being unable to cover all known nests each week, the ground observer was slower to identify an in-use nest, leaving it potentially vulnerable to disturbance.

Figure ES-13. Chart Showing the Mean Number of Nests (+SD) Surveyed Each Week During the Early Season.

COST ASSESSMENT

The table below provides a side-by-side comparison of the two sUAS, UAS, on-the-ground monitor and helicopter. Due to the unique circumstances faced during this demonstration, it is assumed that the additional cost for Government support for waiver and oversight would not be necessary for future projects.

Table ES-1. Cost Comparison of Methods with Government Support for Waiver

Cost Elements	sUAS-DJI Matrice	sUAS- E900	UAS	On-The-Ground	Helicopter
Platform	$ 18,139	$ 5,500	NA	NA	$ 216,000
Payload	NA	$ 5,895	NA	NA	NA
Batteries/Chargers	$ 1,528	$ 1,651	NA	NA	NA
Binoculars, scope	$ -	$ -	NA	$ 2,000	$ 2,000
Transportation *(to-from observation locations)*	$ 3,000	$ 3,000	NA	$ 3,130	
Maintenance/Repair	$ 256	$ 893	NA		
Monitoring Labor	$ 55,346	$ 48,840	$ 10,910	$ 14,715	$ 8,640
Waiver Development (*contractor*)	$ 7,000	$ 7,000	NA	NA	
*Govt. waiver prep and sponsor/training/oversight of flights	$ 79,557	$ 61,249	NA	NA	NA
Total	**$ 164,826**	**$ 134,028**	**$ 10,910**	**$ 19,845**	**$ 226,640**

** Cost specific to this project as a result of DoD Memo banning COTS sUAS and FY19 NDAA prohibiting the procurement or operation of Chinese made sUAS.*

2353 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The most significant cost driver is DoD Army sUAS policy. The platform/payload must meet Department of Army cyber security requirements. Each platform must undergo an evaluation and provide an Exemption to Policy (ETP) also referred to as a waiver, to operate in restricted airspace. The cost associated with obtaining an ETP includes labor to develop the ETP application package *(Standard Operating Procedures, System Safety Management Plan, and Memos),* upload through SIPR, and track through the system. The waivers are only for six months. In addition, each sUAS must have an Airworthiness Release.

The prohibition on foreign made sUAS impacts costs because the U.S. market is still developing and has not yet produced a cost competitive commercial sUAS to compete with foreign made sUAS. As the U.S. market matures and purchases increase, this will begin to bring the costs down.

Costs were not directly assessed for much of the UAS platform team, as the operation of the UAS platforms are part of a larger installation program and were made available for the study on a non-interference basis.

Costs are based on golden eagle monitoring on a MRTBF with vast distances between nests and rugged terrain. Breeding season begins in February and goes through June, allowing for a range of temperatures and weather conditions.

The cost comparison assumes that both the sUAS and on-the-ground monitoring start and return from the same location. The time to survey nests and return to the starting location has been recorded.

Industry data on life expectancy of an sUAS is between one and two years or ~200 flights. When first envisioning this project, it was thought that the sUAS would be most cost-effective and could replace the current approach of on-the-ground monitoring. The results from the demonstration show that the use of an sUAS is a good tool to have available but may not yet be able to cost-effectively replace on-the-ground monitoring. However, the sUAS provides benefits over that of the on-the-ground monitor such as photos which can be used to study and accurately age the chicks. The sUAS can also cover more territory than an on-the-ground monitor and access nests that are too high or at a difficult angle to see from the ground. In addition, some of the costs associated with this demonstration can be reduced or eliminated in future use cases, such as costs associated with government waiver oversight. As the cost of the sUAS system is reduced and the policy surrounding flying the sUAS in DoD airspace is streamlined or eliminated, it may become cost-effective compared to on-the-ground monitoring. The use of sUAS compared to helicopter use is cost competitive.

IMPLEMENTATION ISSUES

A major implementation issue with the use of sUAS in DoD airspace involves obtaining an AWR and Exemption to Policy (ETP). This policy seeks to prevent the use of foreign made sUAS based on cybersecurity vulnerabilities. Both approvals take time to develop, review, and obtain approval. Under the 2019 DoD Army policy, a modified DJI Matrice 600 was used to monitor golden eagles after obtaining an ETP. However, because of the FY 2020 NDAA, Section 848 Prohibition on Operation or Procurement of Foreign-Made Unmanned Aircraft Systems, the procurement or use of Chinese made sUAS was prohibited. This led to the use of a different sUAS platform. Each change of platform requires a new AWR and ETP. The ETP can only be granted for six months at a time and the time to obtain an approval may take 45-60 days minimum.

2354 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The sUAS platform used for observation and data collection has real potential for becoming a quick, cost-effective way to monitor the progress of nesting birds in hard-to-reach places. For this platform to work efficiently and in a manner that collects the best data, some points described below had been found over the past two years to help improve the use of this platform.

Good metadata and a member of the team that has experience with eagle behavior and good knowledge of the territory is key to obtaining useful data. A trained eye for these sUAS platforms was able to compensate for finding nests with sometimes less than ideal video streaming quality or lighting situations. A profile containing pictures from multiple angles and distances and GPS coordinates of known nest in the territory was critical to confirming nest locations and to reduce the time that the sUAS team spent locating nests during a flight.

The UAS observation method was the most uncertain upon the start of the 2019 nesting season, and it proved to be unreliable as a method of weekly nest observations due to scheduling and payload restrictions. RIAC allowed the use of their students and platforms on an as-available basis, and other missions, weather concerns, or maintenance frequently bumped nest observations off the schedule. In addition, the sections of airspace the students were scheduled for were often not over the desired areas of range containing eagle nests to be surveyed. It became clear to the DPG Team that rather than using the UAS as a stand-alone observation method, it would be more useful as a precision tool for obtaining rapid nest observations in areas with no ground access or with critical range use planned within the next two weeks.

If the nest location was well known, the UAS was by far the fastest and most efficient observation method due to lack of drive and hiking time between observation points. However, the nature of the platform's flight and approach patterns made detailed nest metadata critical to the success of the survey. UAS platforms must determine an approach angle and loiter point for a territory observation from several kilometers away, requiring the observation team to have precise knowledge of the nest's location reference data, elevation, aspect, bearing from the ideal viewpoint, and topographical inclusion before the nest can be found. The UAS observation team found that landscape level photos combined with detailed descriptions of a nest's location were sufficient to allow for a successful survey.

1.0 INTRODUCTION

1.1 BACKGROUND

Dugway Proving Ground (DPG), located in remote west-central Utah, serves as a Major Range Test and Facility Base (MRTFB) test site for chemical and biological defensive testing, battlefield smokes, and obscurants. In addition, DPG is home to multiple breeding pairs of golden eagles, which are protected under the Bald and Golden Eagle Protection Act (BGEPA) and the Migratory Bird Treaty Act (MBTA). Due to these regulatory drivers, the presence of an eagle nest has the potential to restrict military testing and training if military activity causes nest disturbance. It is therefore vital to the function of DPG and similar DoD testing and training ranges to fully understand the location and status of in-use eagle nests or territories on military lands.

Current survey techniques of nesting golden eagles on DPG and active DoD training properties require long-distance viewing of each nest from the ground at least weekly, which is both time-consuming, costly, and may not always provide a definitive status of nest changes from incubation to hatching, number of nestlings, nestling condition, etc. *(Weissensteiner and Poelstra 2015)* due to views from the ground. Finding new nests is driven by bird behavior, luck, or significant amounts of time and effort spent traversing rugged terrain on foot. Currently, ranges are required to err on the side of caution if the status of an eagle nest is uncertain, which may lead to increased range closure times. Using both military-grade and commercial Unmanned Aircraft Systems (UAS)/Small Unmanned Aircraft Systems (sUAS), it is possible to obtain highly accurate locations and status updates of in-use golden eagle nests on DoD lands; data that is critical to maintaining open testing and training ranges for as much time as possible in the eagle nesting season *(Chabot and Bird 2015, Hodgson et al. 2016, Junda et al. 2015, Weissensteiner and Poelstra 2015).* The sUAS/UAS can be used to detect new nests in areas that are difficult to see or access from the ground, as well as count nestlings and track nesting milestones in a noninvasive manner not previously possible *(Weissensteiner and Poelstra 2015).* All of this can be accomplished with greatly reduced disturbance to the nesting pairs *(through reduced time in the area),* crucial to the success of sensitive nesters such as the golden eagle *(Chabot and Bird 2015, Scobie and Hugenholtz 2016, Weissensteiner and Poelstra 2015).*

1.2 OBJECTIVE OF THE DEMONSTRATION

Select Engineering Services (SES), in coordination with DPG, the Rapid Integration and Acceptance Center (RIAC), Threat Systems Management Office (TSMO) and HawkWatch International (HWI), hereinafter referred to as the DPG Team, developed this technology demonstration to demonstrate the use of sUAS/UAS as a cost-effective way to monitor golden eagles on military installations. Currently, it takes approximately 960 hours to conduct on-the-ground monitoring of eagle nests for approximately six months *(based upon actual numbers provided by DPG and SES experience).* Much of this time is spent traveling to and from remote sites either by foot or truck. The primary objective was to reduce the total hours required to monitor the nests and evaluate the cost-effectiveness of using sUAS/UAS over in-person ground-based monitoring. Other objectives of the demonstration included the following:

- Efficiencies of scale to monitor more nests in less time for a lower cost
- Demonstrated the effectiveness of sUAS/UAS versus on-the-ground observation

2356 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Improved quality of still photos and videos for further analysis
- Demonstrated use of sUAS/UAS as safe and low disturbance to the eagles
- Demonstrated use of sUAS/UAS to enable greater access to the nest and ability to collect more detailed data
- Demonstrated use of sUAS/UAS as more efficient in finding nests in particular settings such as hidden/remote terrain

1.3 REGULATORY DRIVERS

Golden eagles are protected under BGEPA and the MBTA. These protections require eagles to be protected against "take," defined as "[to] pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, molest or disturb." In addition, the protections against "take" extend to the nests and eggs of eagles, as well as the adult birds. The conservation status of the golden eagle is currently stable globally, but declining regionally, in both western and eastern U.S. populations *(Hoffman and Smith 2003, Katzner et al. 2012, Smith 2008)*. Additionally, a recent review by the U.S. Fish and Wildlife Service (USFWS) upheld concern over the population status of the golden eagle *(USFWS 2016a),* leading to a "no net loss" standard in the recent revision to the "Eagle Rule" *(USFWS 2016b).* This standard essentially prohibits any "take" of golden eagles or their nests without offsetting such take through the permitting framework. To prevent accidental take of golden eagles, DPG is obligated to monitor its existing population of nesting golden eagles and avoid disturbance, except in cases of specific permitted activities. As DPG can monitor its golden eagle population more effectively and efficiently, the installation will be able to operate with minimal concerns for incurring accidental take.

2357 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2.0 TECHNOLOGY/METHODOLOGY DESCRIPTION

2.1 TECHNOLOGY/METHODOLOGY OVERVIEW

The DPG Team conducted weekly golden eagle nest surveys on DPG during the 2019 and 2020 nesting seasons to compare the effectiveness of three "survey systems": 1) a ground-based human observer, 2) a commercially available sUAS, and 3) one or more military-grade UAS platform(s). These nest surveys were conducted as a blind study; none of the three teams of observers encountered one another in the field. None exchanged information concerning the nest surveys, and none had any access to data generated by surveys conducted by any of the other teams.

Golden eagle nest surveys are typically performed by one observer that travels to 11 territories to observe and note status of nesting. A second observer is sometimes used for safety if the terrain/location warrant it. Equipment includes high power binoculars/scope. All observations are documented, on paper, but no pictures or videos are taken. On-the-ground observers are required to undergo unexploded ordinance training (UXO) administered by Dugway range safety officers as well as basic coordination, navigation, and radio ops training specific to DPG.

The sUAS platform DJI Matrice 600 *(Figure 1)* was originally proposed for this project. However, the 23 May 2018 DoD Memo, "Unmanned Aerial Vehicle Systems Cybersecurity Vulnerabilities" was issued, suspending the use of Commercial Off-the-Shelf (COTS) sUAS. In response, a DJI Matrice was procured with an approved DoD software patch, through the Army Ground Aerial Target Control System (AGATCS), in partnership with the Threat System Management Office (TSMO). DJI Zenmuse Z30 cameras were used as the operational payload, with 32x optical zoom allowing for long-range HD observations. This system was approved for use during the 2019 nesting season.

Figure 1. DJI Matrice 600 Pro

2358 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

However, in December 2019 the National Defense Authorization Act (NDAA) was signed which called for a complete ban on the procurement and/or use of Chinese made sUAS platforms by DoD programs except in the case of sUAS counter-defense testing *(Appendix 2)*. This language was strictly interpreted to prevent the use of the modified DJI Matrice that was used the previous year. This led the DPG Team to seek out another option. Through discussions with TMSO, an alternative sUAS was identified for use, the E Mergent RC E900 platform *(Figure 2)*. The two E900s were integrated with Sony FCB-EV7520A camera payloads.

Figure 2. E Mergent RC E900

Table 1 below provides a comparison of the two platforms. The two payloads were technically comparable but the Matrice was designed as an integrated system whereas the E900 was integrated with a camera payload after manufacture. The primary differences between the two were the transmission distances, operating frequencies, and the SD card which was in the camera on the Matrice and in the controller tablet of the E900. These differences led to a significant degradation of photo quality from the E900.

2359 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 1. A Comparison of the Two sUAS Platforms: The Modified DJI Matrice 600 in 2019 and the E900 Used in 2020

	DJI Matrice 600	E900
Max Transmission Distance	3.1 miles	1.5 miles
Frequency	5.8 GHz	2.4 GHz
Payload Specifications	30x Optical Zoom + 6x Digital zoom 2.13 Mp 1080p Tablet Tap Zoom supported	30x Optical zoom + 12x Digital zoom 2.13 Mp 480p *(functional resolution)* Separate controller for camera
Camera and Interface Abilities	Auto/Manual – Focus, Shutter Priority, Bright Compensation SD card Supported	Auto/Manual - Focus, Shutter priority, Bright Compensation SD card in controller tablet
Batteries	6x 5700 mAh	1x 6S 2200 mAh battery Battery weight – 2490 g *(+/-20g)*
Estimated Flight Time (minutes)	~25 min	~20 min
Max Takeoff Weight (payload capacity)	15.5 kg Payload Capacity - 5.5 kg	10.5 kg Payload Capacity – 4.5 Kg
Max Wind Resistance	18 mph	20 mph

The sUAS team consisted of a pilot-in-command, operator, and observer who was also an ornithologist with in-depth knowledge of the Dugway range and eagles in the area. All three members of the team completed training before the study began consisting of UAS flight theory, platform components, flight controls, operation, troubleshooting techniques, and supervised flight training administered by TSMO. All members of the team underwent unexploded ordinance training (UXO) administered by Dugway range safety officers as well as basic coordination, navigation, and radio ops training specific to DPG.

DPG is also home to the Rapid Integration and Acceptance Center which was established by the Project Manager Unmanned Aircraft Systems to create a single location where unmanned and manned aircraft could complete end-to-end testing and integration. DPG coordinated with RIAC to conduct monitoring flights when they were not conducting mission flights. RIAC identified a military UAS platform that would be most suitable for this type of flight plan. There are approximately 24 Continental United States Army installations with UAS that could potentially be used for monitoring of raptors or other natural resources as part of their ongoing training of UAS pilots.

The UAS was operated by UAS pilots, supported by an ornithologist who provided coordinates and identification/analysis of nests.

2.2 TECHNOLOGY/METHODOLOGY DEVELOPMENT

The DPG Team's technical approach was to demonstrate the cost-effective use of sUAS/UAS to monitor golden eagles by a direct blind comparison between on-the-ground monitoring and sUAS/UAS overflights. A flow diagram for the methodology proposed can be found in Appendix 3, and a detailed overview of the methodology developed can be reviewed in section 5.4 *(Field Testing)*.

2360 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2.3 ADVANTAGES AND LIMITATIONS OF THE TECHNOLOGY/ METHODOLOGY

Currently, on-the-ground monitoring includes one observer visiting each of the 11 territories once or more per week until occupancy is established, the in-use nest is identified, or sufficient monitoring and time of year eliminates the possibility of initiation of nesting activity. In-use nests are tracked with in-person visits once per week for the duration of the breeding season until nest fledge or demonstrable failure. This method is relatively reliable with repeated visits, but is time-consuming, costly, and may not always provide a definitive status on a given day of observation. Also, the changes in nest status are not immediately available, which can cost the military valuable operation days on closed ranges.

The demonstration studied two different sUAS platform/payload systems: a DJI Matrice 600 Pro with a Zenmuse Z30 payload in the 2019 nesting season, and an E Mergent RC E900 prototype with a Sony FCB-EV7520A payload in the 2020 nesting season. The two platforms performed very differently during each nesting season, and each showed its own strengths and limitations.

The DJI Matrice is a commercial off-the-shelf product, and as such was well designed and easy to use. The Matrice was stable and reliable in the field, with robust trouble-shooting procedures and documentation. The integrated Zenmuse camera system provided HD on-board photo and video recording of nests over distances of over 800 meters. The Matrice maintained flight control and video transmission over distances of up to 3 miles, far greater than typical line of sight limits, allowing for remote or obscured nests to be observed efficiently. However, the bulky battery system and low tolerance for temperature extremes limited the Matrice in particularly rugged conditions. The Matrice is also manufactured in China, and as such it is currently restricted from use in DoD restricted airspace except for use in counter-sUAS defense applications. Therefore, this system is no longer available for use in DoD restricted airspace.

The E Mergent RC E900 is a prototype sUAS platform developed for custom DoD applications in partnership with TSMO. The main advantage of the E900 over the commercial DJI Matrice is that it is American made, and as such is currently eligible for consideration of the DoD issued flight waiver. It is also highly customizable to a specific project's needs and can be modified and repaired at will with sufficient technological expertise. However, the E900 is not a fully realized commercial product, and as such it was less refined and reliable than the Matrice. The E900 also lacked the ease of use of the DJI payload controls and software. It was determined that the current iteration of the E900 used for the demonstration lacked the long-range transmission capabilities required, as well as possessing inadequate video stabilization and control operations. Integrating a third-party payload into the E900 system resulted in limited video resolution and recording capabilities. The after-manufacture integration of the camera onto the platform created some photo quality issues. The SD card was located in the controller tablet instead of on the camera, therefore photos/videos would be transmitted to the SD card, which required the images to be reduced from 1080p to 480p.

Furthermore, both sUAS platforms have risk minimization features. Both platforms include user friendly, intuitive flight controls with programmable altitude restrictions, horizontal geofencing, and GPS hold mode to insure platform stability in windy weather. An added GPS failsafe includes a return to home/auto land switch on the controller that initiates an autopilot to land the platform at its original takeoff location with no input from the pilot. Both platforms include real time information such as distance from controller, heading indicator, altitude above takeoff location, and battery performance all on one display. This heads-up information allows separation from nesting areas to help prevent "take" of the birds, or to stay clear of restricted airspace.

2361 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The MQ-1C Gray Eagle was also used when available for nest monitoring in both the 2019 and 2020 nesting seasons *(Figure 3)*. The Gray Eagle fleet on DPG underwent a significant upgrade to their payload systems during the fall of 2019, resulting in much higher resolution video for the 2020 season. This is the first time a military UAS platform has been used to monitor nesting raptors. It was theorized that the high speed and very long observation ranges of the platform would allow it to survey many territories both quickly and thoroughly, with no impact to ground operations in the area. The thermal imaging capabilities of the Gray Eagle platform were also intriguing as a method of detecting chicks *(before they develop insulating adult plumage)*. It was also theorized that student pilots training with RIAC would benefit from the high difficulty of locating eagle nests in cryptic terrain, especially given a mission structure mimicking what they would encounter in theater. Because the Gray Eagle was not always available for monitoring, it was difficult to obtain comparable data.

Figure 3. MQ-1C Gray Eagle

Although not specifically included in the demonstration, helicopters can also be used to monitor nests. This method, as with the other surveying techniques, has its pros and cons. The greatest advantage of using a helicopter as an observation platform is its ability to move quickly from territory to territory. With a trained spotter on board and with the use of optics, nest status can be quickly recorded from an advantageous perspective in hard to reach places. A trade-off of the helicopters speed and mobility is the noise of the aircraft increasing the potential for nest and eagle disturbance.

2362 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

These disturbances may skew the data as disruptions of a nesting pair of eagles may result in failure of a nest in a worst-case scenario, especially when monitoring frequently throughout a season as required by DPG's ongoing range activities. The higher perspective and fast movement of the helicopter may also limit the observer's ability to search the area for eagles when first entering a territory, which makes determining early season occupancy difficult. This practice of using optics to search an area when first entering a territory has proven effective in the past of helping an observer's ability to track an eagle to its nest. Furthermore, from a logistical standpoint, the scheduling availability of range airspace for the helicopter to be cleared to fly would be inconsistent at best, as the nesting period of the eagles fall during a typically busy time for range operations. As a final consideration, there is a significant risk to human health and safety when monitoring eagle nests via a helicopter, due to the inherent dangers of flying close to cliff faces and low through rugged terrain. The very high cost of both pilot and helicopter needs to be taken into consideration when contemplating using a helicopter for territory observations and data collection.

2363 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

3.0 PERFORMANCE OBJECTIVES

The following performance objectives were developed as the primary criteria by which the DPG Team could assess the success of the sUAS/UAS platforms as nest monitoring tools. The specific benchmarks identified are focused on reduction of time required to monitor nests, increase in number of nests surveyed, and increase in precision of results, all in comparison to the standard ground observer.

Table 2. Performance Objectives

Performance Objective	Metric	Data Requirements	Success Criteria
Quantitative Performance Objectives			
Total amount of time necessary to determine the early season status of all known nests	Amount of time necessary for the method of observation to determine early season status of all known nests	Exact start and ending times of daily survey for each method of observation	sUAS/UAS time to determine early season status < or = in-person time to determine status
Total number of in-use nests identified	Number of in-use nests the method of observation is able to identify	Weekly report of nest activity status for each known territory by each method of observation	Total number of nests identified by sUAS/UAS > or = number of nests identified in-person
In-use nest date of identification	Accuracy of the method of observation in determining nest activity	Dates of territory visits recorded in conjunction with nest status for each method of observation	Date of identification the same or earlier for sUAS/UAS than in-person
Nest failure date of identification	Accuracy of the method of observation in detecting nest failure	Dates of territory visits recorded in conjunction with nest status for each method of observation	Date of identification the same or earlier for sUAS/UAS than in-person
The total amount of time necessary to update the status of in-use nests	Amount of time necessary for the method of observation to update the status of a known in-use nest	Exact start and ending times for territory and nest visits for each method of observation	sUAS/UAS total time spent to update nest status < or = time spent in-person
The number of previously unknown alternate eagle nests found within the 11 territories	Ability of the method of observation to detect new or previously unknown eagle nests	Each new nest observed recorded by each method of observation	Total number of new nests found by sUAS/UAS > or = number of nests found in-person
Differences in hypothetical mission impact *(in days)* and nest protection based on restrictions imposed and lifted due to monitoring	Precision of the method of observation in determining dates of activity and failure/fledge	• Dates of perceived activity and failure/ fledge recorded by each method of observation • True dates of nest activity and failure/ fledge recorded by camera equipment directly observing nest	• sUAS/UAS indicated days of mission impact < or = in-person indicated days of mission impact • sUAS/UAS indicated days of nest protection most similar to days of actual nest activity
Qualitative Performance Objectives			
Quality of video/photos to document occupancy and status	Ability of the method of observation to gather proof of nest activity status	Photo/video documentation of each in-use nest by sUAS/UAS and in-person observers	sUAS/UAS gather higher quality video and photos to document nest activity than in-person observers

2364 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

4.0 SITE DESCRIPTION

4.1 SITE LOCATION AND HISTORY

Dugway Proving Ground is located on the southern end of the Great Salt Lake Desert and covers 798,214 acres, serving as a test site for chemical and biological defensive testing, battlefield smokes and obscurants *(Figure 4)*. DPG was activated for military use in 1942 to serve as a proving ground for the testing of chemical weapons. Chemical, biological, and explosives testing have been conducted within DPG. Open air testing of chemical and biological agents was conducted until 1969, after which all chemical and biological warfare testing was confined to sealed chambers. Open-air testing of decontamination methods, contamination avoidance, and evaluation of threat dissemination methods, including the use of biological and chemical simulants in place of biological and chemical agents, has been done at DPG since 1969. In addition, DPG was first opened to Army Reserve Component training in 1969. Ground training on DPG includes a wide variety of activities at DPG, ranging from 12-soldier weekend activities to 3,000- to 4,000-soldier tactical exercises lasting up to several weeks.

2365 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

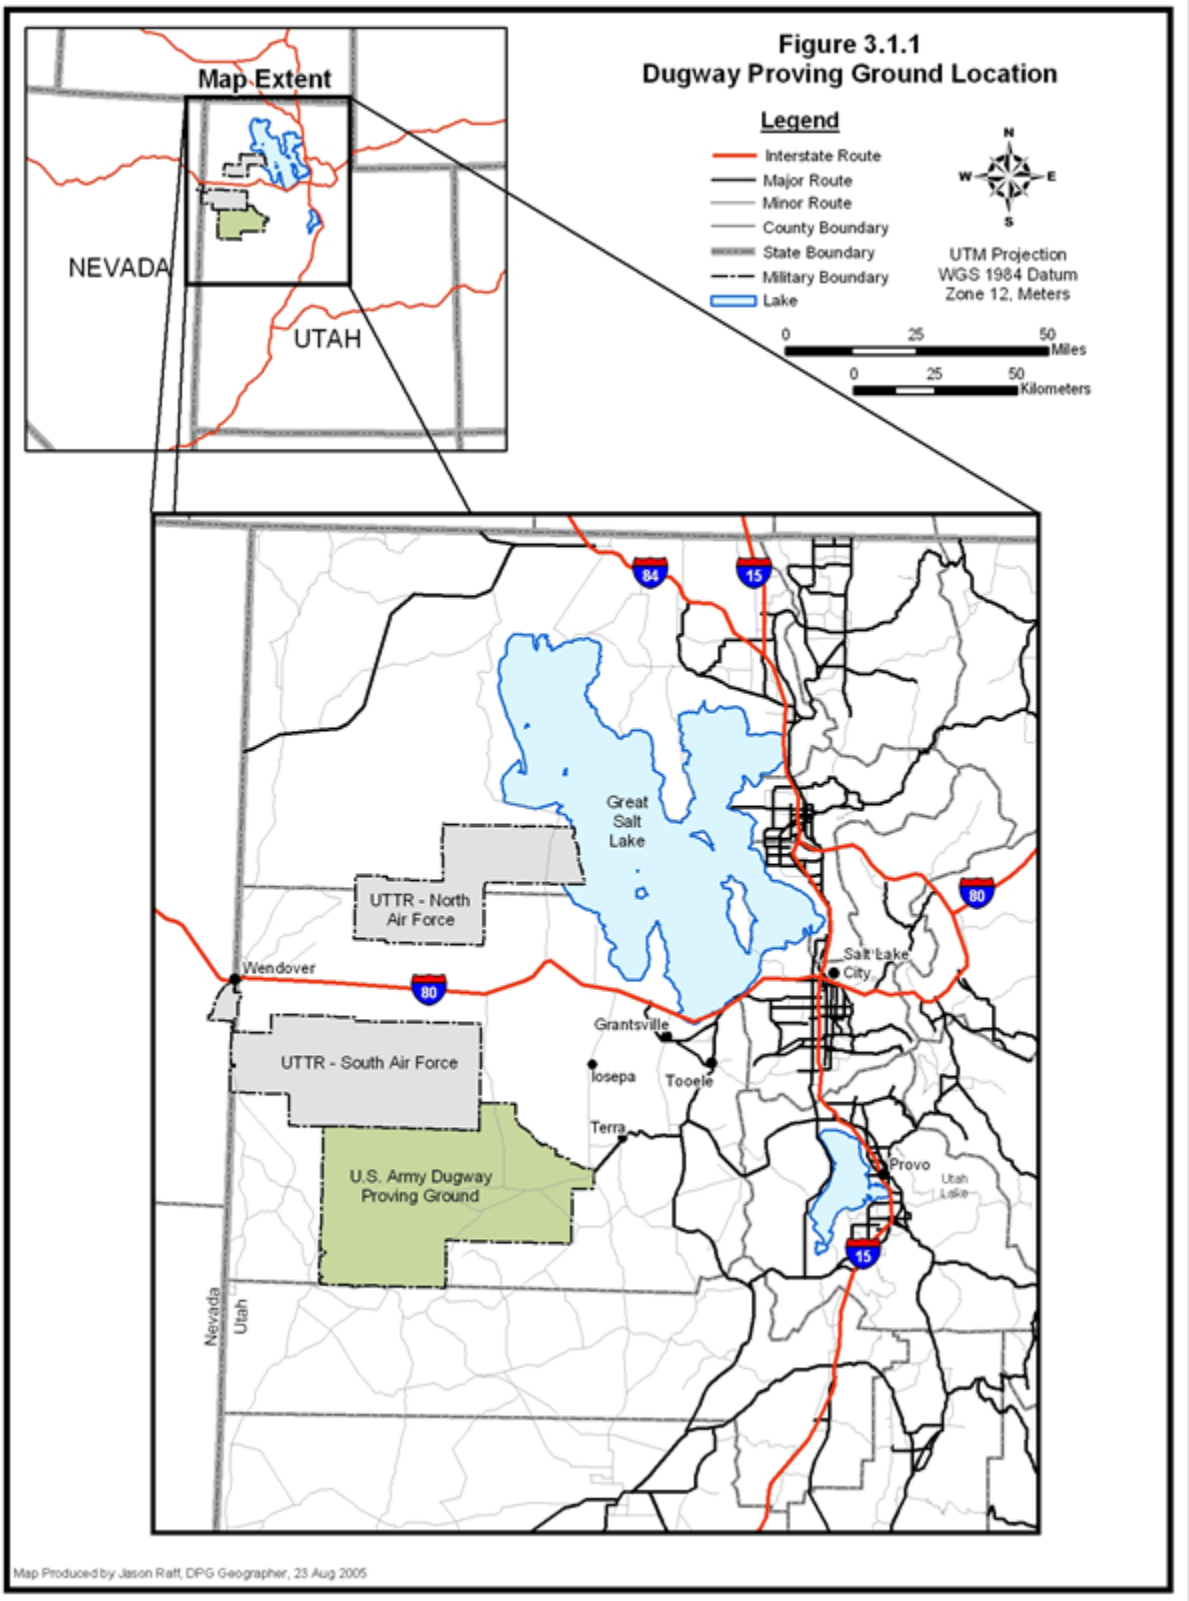

Figure 4. Map of DPG Showing Location Within UT

2366 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

4.2 SITE CHARACTERISTICS

DPG is within the Great Basin subdivision of the Basin and Range Physiographic Province. The Basin and Range Physiographic Province includes parts of Idaho, Oregon, Nevada, Utah, California, Arizona, New Mexico, and northern Mexico. This province is characterized by a series of mostly isolated north-south trending mountain ranges that are separated by wide desert plains *(Press and Siever 1982).*

Most of DPG lies within the Great Salt Lake Desert, with mountains and low-lying basin areas covering remaining portions of DPG. DPG is bordered to the northeast by the Cedar Mountains and to the south by a series of ranges and valleys, the closest of which is the Dugway Range. The Onaqui Mountains and Davis Mountain lie to the east of DPG. The Deep Creek Range lies to the west and marks the boundary of the Great Salt Lake Desert. The Stansbury Mountains lie to the northeast of the Cedar Mountains.

Relatively extensive basin areas are broken by the topographic relief of the Cedar Mountains, Little Davis Mountain, Simpson Buttes, Camels Back Ridge, Wig Mountain, Granite Peak, and Sapphire Mountain. There are no large perennial surface water bodies that lie within or border DPG. However, two large playas are located in the western and southern portions of DPG, the DPG Playa, and the Downwind Grid Playa. Vegetated and non-vegetated sand dunes are also located in the eastern and central portions of DPG and along DPG's northern and western boundaries.

DPG is in a semi-arid, continental, steppe region, or high desert known as the Great Basin Desert. This region is often referred to as a cold desert due to its mid-latitude location. Typically, winters are cold; summers are hot and dry with a high evaporation rate; and most precipitation falls in the spring *(Dugway Proving Ground 2003a).*

Other weather characteristics typical of the DPG area include frequent electrical storms and occasional dust storms in summer and temperature inversion conditions in winter. Temperature inversion conditions occur when cold Arctic air spills into the area, wind speed is low, and contrary to the normal pattern, air temperature increases with height above the ground surface. Surface airflow is reduced and any tendency toward reduced air quality is aggravated under these conditions *(Dugway Proving Ground 2003a).*

Weather patterns at DPG are influenced by terrain. Most of DPG is relatively flat because it consists of a former lakebed *(the former Lake Bonneville of which the Great Salt Lake is a small remnant).* Interspersed in the flat terrain are abrupt, often pinnacle-like mountains, which are cooler and receive more precipitation than surrounding flatlands. They influence local weather patterns by channeling winds and promoting up- and down-slope conditions in mornings and evenings, respectively *(Dugway Proving Ground 2003a).*

Local wind patterns are governed by differential heating and cooling of higher elevations relative to flatlands and by regional weather. These patterns usually include the onset of southeasterly or southerly downslope flow at night that persists into morning, which transitions into northwesterly through northerly flow with daytime heating. There are two periods of relative atmospheric stability in early morning and early evening hours. These patterns are marked in summertime but weak or absent in winter, due to differences in the amount of heat in the form of solar radiation received seasonally and the tendency of snow to reflect solar radiation away during winter *(Dugway Proving Ground 2003a).*

2367 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Monthly average temperatures for the Ditto Technical Center for the period 1950 to 1998 range from 77.9° F in July, which is the hottest month, to 27° F in January, which is the coolest. Daily extremes for each month show a substantial range. For example, for July the daily extreme high is 109° F and the extreme low is 37° F. Similarly, the daily extreme range for January is 91° F. Large temperature fluctuations recorded between day and night and seasonally are typical of the area's arid continental climate *(Dugway Proving Ground 2003a).*

Precipitation data for the Ditto Technical Center for the period 1950 to 1998 show that mean annual precipitation is about 8 inches with a low of about 3 inches and a high of about 15 inches. Wettest months are March, April, and May, followed by October. Snowfall occurs November through March; however, snow may persist at mountain elevations for much longer periods than on flatlands *(Dugway Proving Ground 2003a).*

The average warmest month is July, and January is the average coldest month. The highest recorded temperature was 109° F in 1998, and the lowest recorded temperature was -29° F in 1989. May is the average wettest month.

Unusual or severe weather conditions, such as fog and cloud ceilings, which limit visibility, occur most often during winter. Thunderstorms or electrical storms occur during summer *(Dugway Proving Ground 2003a).*

The map below *(Figure 5)* shows the 2018 known eagle nest territories. These territories are significant distances between them and cover a wide range of terrain and are limited by road access.

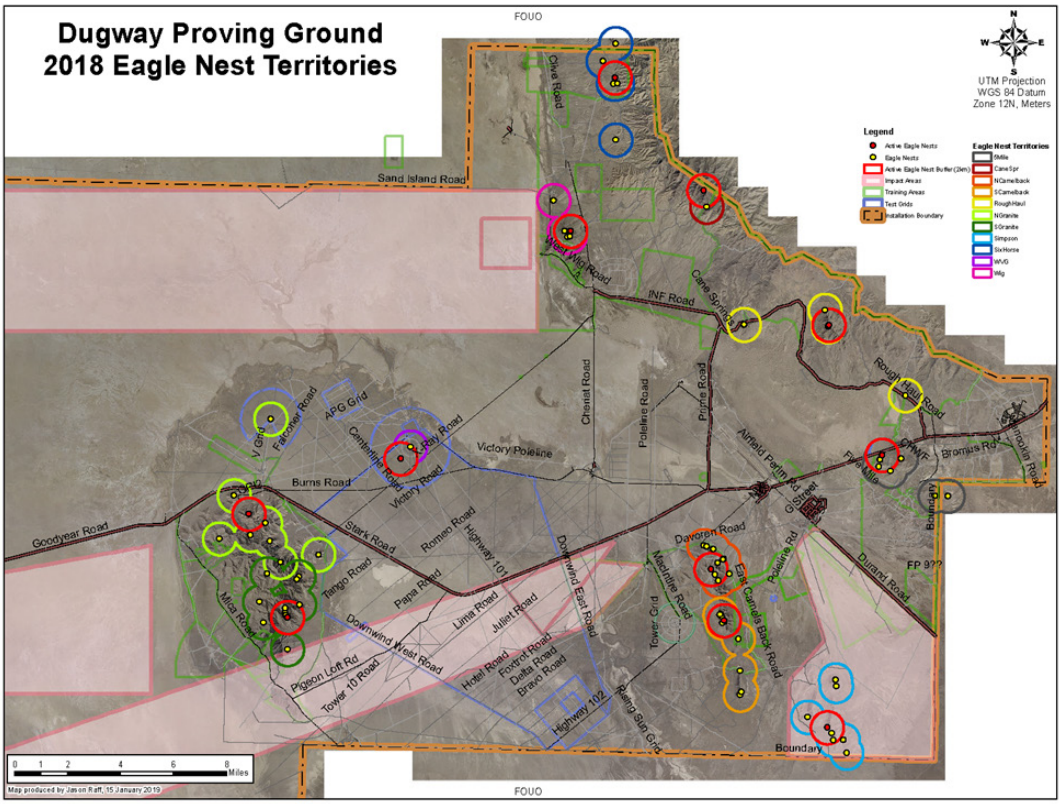

Figure 5. Map of Golden Eagle Nests and Territories at DPG

2368 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

5.0 TEST DESIGN

5.1 CONCEPTUAL TEST DESIGN

The DPG Team conducted weekly golden eagle nest surveys on DPG during the 2019 and 2020 nesting seasons to compare the effectiveness of three "survey systems": 1) a ground-based human observer, 2) a commercially available small sUAS, and 3) one or more military-grade UAS platform(s). The ground-observer was a single vehicle-based biologist; the sUAS system included three personnel *(commercial pilot, observer, and biologist for video monitoring);* and the military UAS required three personnel *(military pilot, military camera operator, and civilian biologist for video monitoring)*. All three biologists associated with each survey approach had comparable familiarity with existing DPG eagle territories and previous eagle nest monitoring experience.

The DPG Team generated territory-specific data sheets that specify known nests within 11 known territories on DPG *(Figure 5),* nest survey order based on historic use patterns, and other detailed survey instructions. The ground observer and the sUAS observation team attempted to survey the same 11 territories relatively close in time, but the biologists associated with each survey system remained blind to each other's findings. The UAS observation team conducted a separate territory and nest survey effort designed to test the platform's capabilities as a precision, on demand survey system for areas with little to no ground access. Two senior DPG environmental staff provided weekly oversight of data collected by all three survey systems and collated survey results to ascertain the weekly "benchmark" status of each territory, and to ensure survey protocols were properly followed. Camera data from a subset of nests were also used to provide retrospective verification and correction of weekly status. Generally, all surveys conducted by the ground and sUAS observation teams occurred on Monday and Tuesday of each week, with Wednesday available as a weather or other make-up day, and Thursday for data review by senior staff. Individual territory surveys by the ground observer and sUAS were staggered to avoid overlap in time. The military UAS observation team conducted surveys as available. Each survey round of co-monitored territories *(i.e., territories "shared" between survey systems, which may vary based on stage of season and performance of individual systems)* were completed by all three platforms within 36 hours of each other, unless weather delays or other unforeseen issues occurred for one or more platform.

Each annual survey was segmented into two time-periods: the "early season", defined as 10 February–14 April *(9–10 weeks)* and the "late season", defined as 15 April–30 June *(12 weeks)*. Survey seasons were selected based on 12 February–19 March "core" egg laying dates *(i.e., 90% of observed values, with 5% tails removed)* back-dated from 1,038 Utah desert nests *(K. Keller, unpublished data)*. The early season end date was set to allow at least two survey rounds after the latest likely lay date based on past data. Similarly, the late season end date was set to encompass 80% fledge age based on the latest likely egg laying date. The primary goal of the early season surveys was to document "Occupied Territories", "In-Use Nests", and "Vacant Territories", while the goal of late season surveys was to track In-Use Nest to "Success" *(at least one nestling surviving to 80% fledge age)* or "Failure" *(terms adapted from Steenhof et al. [2017])*. During the early season, all 11 territories were surveyed every two weeks *(e.g., six one week, five the next)*. In contrast, late season surveys were restricted to In-Use Nests found during the early season surveys, plus any territories with unresolved status.

2369 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

For ground and sUAS survey systems, independent teams attempted to survey each nest from outside an 800-meter horizontal protective buffer *(as widely prescribed on public lands and suggested by Romin and Muck [2002])*. If topography prevented clear viewing at that distance, these survey systems were authorized to approach to within 400 meters of a nest, but only as close as necessary to confirm nest status. The "incursion" view distance was recorded. Closer approaches to confirm inactive nests were allowed to facilitate area nest searching. Biologists associated with each survey system recorded eagle response behavior *(i.e., any agitation or flushing observed while conducting nest surveys).*

Surveys conducted for each platform followed specific territory and nest survey protocols to ensure comparable methods were employed and to facilitate the capture of detailed time-keeping records associated with specific survey tasks. Biologists for each survey system recorded total daily "Survey Time", which began upon departure from English Village *(ground and sUAS)* or initiation of take-off from the DPG airfield *(UAS)* and continued until return to same location at the end of the survey effort. For each platform, "Territory Survey Time" was noted, starting when entering into a 2-km buffer around known nests associated with each territory, and continuing until status was confirmed, and the survey was complete, or a 3-hr time limit was reached. Time spent within each territory involved an "Area Search" *(general scanning overall area for adult and nesting evidence),* "Nest Search*" (prescribed order survey of known nests),* and "Extended Search*" (searching for new or uncatalogued nests)* was also recorded. Surveyors used standardized terminology established in this document and photographic guides to age eagle nestlings *(Driscoll 2010, Hoechlin 1976).* The specific protocols associated with each survey period and specific survey tasks are detailed in the following section. These approaches were further reinforced by complementary flow charts *(Appendix 3),* and territory-specific data sheets.

5.2 BASELINE CHARACTERIZATION AND PREPARATION

Three surveyors with high levels of previous experience surveying golden eagle nests for this study were selected. One ground observer had 7 years of golden eagle nest survey experience in the West Desert prior to the start of this study, including 4 years surveying nests on DPG. The sUAS observer had 4 years of golden eagle nest survey experience, all conducted on DPG. The UAS observer possessed 6 years of golden eagle nest survey experience in the West Desert, overlapping with 4 years surveying in other parts of Utah, and 1 year of experience in southern Idaho before this study. Prior to the start of each field season, each observer reviewed the data collection protocols and held a briefing to discuss field procedures and relevant survey details associated with individual territories. Datasheets included territory and nest maps to aid all observers in locating nests *(Table 3).* At the end of year one, a debriefing was held to discuss survey issues encountered by each observer. It was found that high angle, distant views from the UAS platforms and limited UAS observer experience with DPG nests seriously limited nest locations in year one. As a result, "mission packets" were created prior to the start of year two, which included recommended UAS approaches, viewing angle, nest elevation offset, and nest photos, where available.

2370 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 3. Status of Golden Eagle Territories on DPG

2015–2018. Nest status was determined by ground observers using binoculars and 60x spotting scopes, equipped with maps showing nest locations and photos of a sub-sample of nests. Territories were considered to contain an "In-Use Nest" if observers detected evidence of a breeding attempt (an adult eagle in incubating posture on a nest, or nestlings), or occupied if a pair of eagles were present in the territory.

Territory Name	# of nests*	2015	2016	2017	2018
Six Horse pass	6	Occupied	**In-Use Nest**	Occupied	Occupied
Cane Springs	2	Occupied	Occupied	Occupied	**In-Use Nest**
North Camelback	12	**In-Use Nest**	**In-Use Nest**	**In-Use Nest**	Occupied
North Granite	8	**In-Use Nest**	**In-Use Nest**	**In-Use Nest**	**In-Use Nest**
Roughhaul Rd	5	**In-Use Nest**	Vacant	Vacant	Occupied
South Camelback	15	Occupied	**In-Use Nest**	Occupied	**In-Use Nest**
South Granite	13	Occupied	Occupied	Vacant	Occupied
Simpson Butte	8	Unknown**	**In-Use Nest**	**In-Use Nest**	Unknown**
West Vertical Grid	4	**In-Use Nest**	**In-Use Nest**	**In-Use Nest**	**In-Use Nest**
Wig Mountain	6	**In-Use Nest**	**In-Use Nest**	**In-Use Nest**	Occupied
Five Mile Hill	7	Vacant	Vacant	Occupied	Occupied

* The number of nest location records is approximate, and includes all documented nest locations, which may include some that have collapsed and no longer exist, or some duplicate nest records.

** Ground observers were not permitted to access Simpson Butte due to unexploded ordnance in the vicinity during 2015 and 2018.

5.3 DESIGN AND LAYOUT OF TECHNOLOGY AND METHODOLOGY COMPONENTS

This project was designed to compare the cost-effectiveness and technical capability of the ground monitor versus the sUAS versus the UAS when monitoring nesting golden eagles. The hypothesis was that sUAS would provide a cost-effective means of monitoring eagles over the traditional ground monitoring due to the amount of area that can be covered in a short amount of time, as well as the use of HD cameras that are able to be positioned at various altitudes and angles to provide the best look into the nest. The sUAS is also a relatively inexpensive, easy to operate platform. Figure 6 below shows the 11 territories that were monitored each season.

The methodology used was based on best practices in the eagle monitoring arena to ensure a blind study with verifiable results. All results were analyzed in conjunction with costs to determine the most cost-effective solution.

2371 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

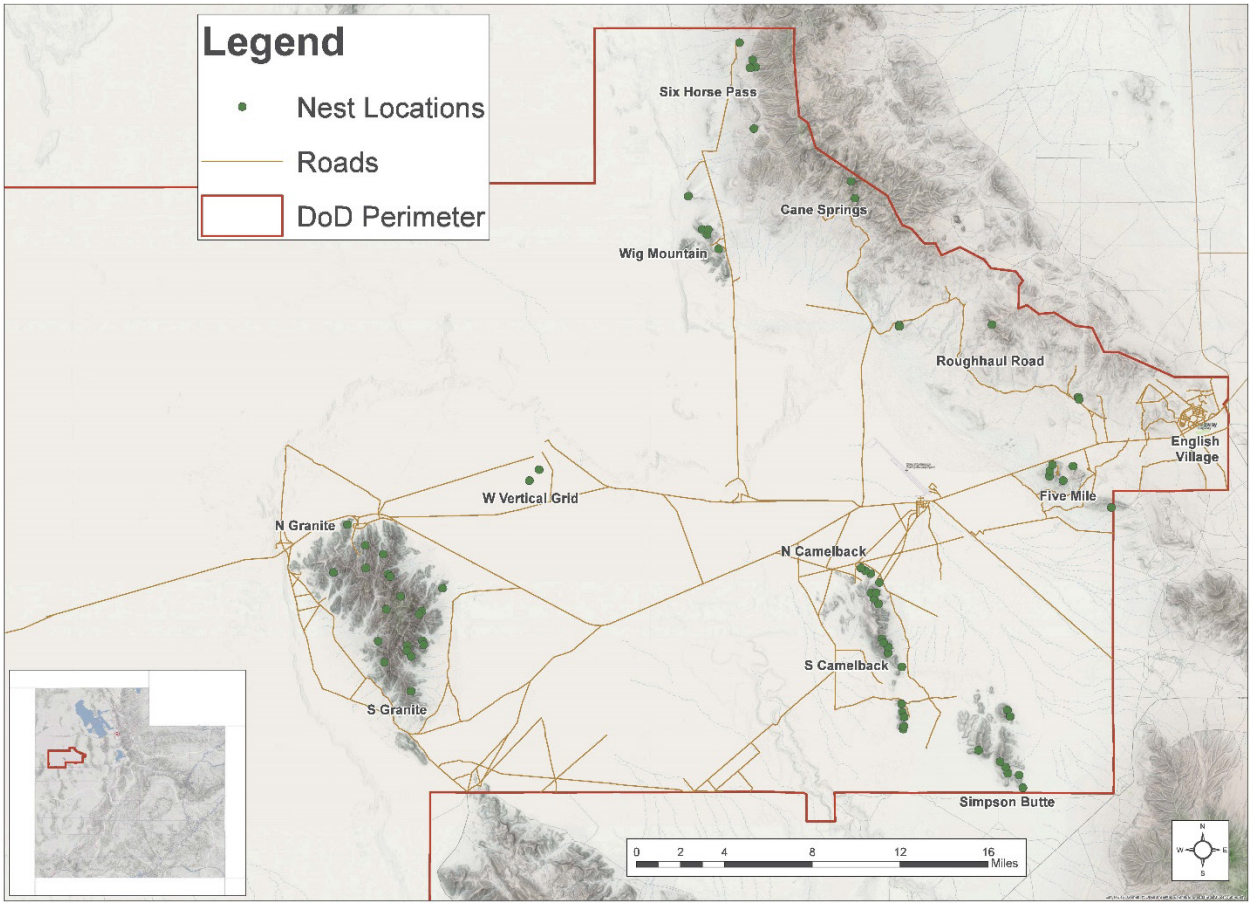

Figure 6. Known Golden Eagle Nest Locations Associated With 11 Territories on DPG

5.4 FIELD TESTING

The following instructions were provided to the observers to guide field observations, in addition to the simplified flow chart of methods provided in Appendix 3.

Early Season: Surveyors will attempt to search all 11 territories every two weeks, with 6 and 5 territories surveyed on alternating weeks, utilizing up to 2 survey days per week, and up to 3 hours search time per territory. Territories will be grouped by location and the ground observer and sUAS team will alternate territory groups between days. Territory survey order within each group will be based upon DPG identified priority areas and optimal time of day viewing conditions. Surveyors will follow strict survey protocols detailed below and visualized by flowcharts in Appendix 3.

Step 1: Determine necessary survey effort level at each territory:

- If first territory survey, or no In-Use Nest found during previous survey(s), attempt complete search below *(Step 2–7)* until territory status is determined or 3-hour time limit is reached for that territory.
- If In-Use Nest present on previous visit, complete Steps 2–4, and then proceed to "In-Use Nest" protocol. This includes nests for which the previous status was "previously In-Use unknown" *(see description in "In-Use Nest" protocol),* until status is resolved.

2372 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- If an In-Use Nest in this territory was previously determined as "failed", do not survey.

Step 2: Record daily "Survey Start Time" when leaving English Village *(Ground/sUAS)* or upon take-off *(UAS).*

Step 3: Record individual "Territory Survey Start Time" when within 2-km buffer around known nests.

Step 4: Navigate to within 800 m+ or adjusted viewing location of first ranked nest(s) *(order prescribed based on survey history).*

Step 5: "Area Search": record stationary time spent searching for free-flying eagles within territory or on ridges *(up to 15 mins).* Time does not include approach drive/fly time to stationary point, but adults observed during approach are noted *(please indicate if observed on approach).*

- No adults seen, proceed to "Nest Survey".
- One adult seen, proceed to "Nest Survey", but adjust nest survey order to begin with known nest(s) within 250 m of adult, survey all other nests in prescribed order.
- Two adults seen off-nest, search any known nest(s) and substrate visible within 250 m of adults for signs of nest tending/eggs. If both eagles remain off-nest for 15 mins, territory survey ends, with times noted, and territory status will be recorded as "Territory Occupied, no In-Use Nest".

Step 6: "Nest Survey": attempt to search all known nests in pre-determined order, with visit-specific modifications as warranted. Each nest is viewed until status is confirmed *(i.e., "In-Use" [adult, egg, or young on nest], "inactive" [not In-Use, based on clearly visible nest bowl/platform, or condition inadequate for nesting], "Unknown" [30 mins viewing viable nest, status unresolved], "Time expired" [territory survey end time reached before status confirmed], or "Not Surveyed").* Evidence of tending/greenery is noted. Record all nest survey time undifferentiated by nest but note if full 30 mins required for individual nests.

- Attempt to survey all known nests in prescribed order (based on nest histories, but adjusted if presence of adult(s) detected during this or previous survey, or recent evidence of tending), until "In-Use Nest" (eggs/nestling/incubating adult) found, two adults seen off-nest, all nests surveyed, or 3 hr time limit reached. If all nests were not surveyed during a previous survey due to time expiration, resume from previous position.
- Up to 5 mins may be spent scanning nearby cliff faces and ridgetops upon arrival at each new viewpoint.
- If an In-Use Nest is found, proceed to "In-Use Nest" protocol (survey ends there, with end times noted). Territory status will be recorded as "Occupied-In-Use Nest".
- If two adults seen off-nest, go to protocol under "Two adults seen", under "Step 5: Area Search" (survey ends there, with end times noted).
- If all nests surveyed without detecting an In-Use Nest, and a single adult has been seen on this or any previous survey, record end of Nest Survey time and proceed to "Extended Search".

2373 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- If all nests surveyed without detecting an In-Use Nest, and no eagles were detected in the territory, record territory status as "Vacant Territory", record end of Nest Survey time and proceed to next territory.

Step 7: "Extended Search": attempt to find new nests when only one adult seen and known nests are not In-Use. Record search time, including time hiking if relevant, and indicate area searched on map.

- Search potential nest substrate and ridges within 250 m of previous adult sightings(s) for potential alternate nests, until an In-Use Nest is found *(go to "In-Use Nest" protocol),* two adults are seen off-nest, the area surrounding the sighting has been adequately searched *(may include hiking for ground observer),* or time expires. Add any new nests found to the end of next territory visit search order unless evidence of tending.
- If an In-Use Nest is found, proceed to "In-Use Nest" protocol *(survey ends there, with times noted).*
- If two adults seen off-nest, go to protocol under "Two adults seen", under "Step 5: Area Search" *(survey ends there, with end times noted).*

Step 8: Record "Territory Survey End Time" when leaving 2-km buffer around each territory (NOTE: 3 hr territory limit begins upon entering 2-km threshold, but may expire during nest survey, extended search, or In-Use Nest monitoring).

Step 9: Repeat Steps 3-8 until all territories allotted for survey in a given day are visited. Ground and sUAS may not survey territories allotted for other survey days to maintain separation of survey platforms.

Step 10: Record daily "Survey End Time" on return to English Village or runway.

Late Season: Surveyors will attempt to visit all In-Use Nests identified in early season every week, plus any carryover territories with ambiguous status until resolution is reached, utilizing up to two survey days per week, and up to a time limit specific to each territory (between 1 and 4 hrs). Territories will be grouped by location and the ground observer and sUAS team will alternate territory groups between days. Territory survey order within each group will be based upon DPG identified priority areas and optimal time of day viewing conditions. Surveyors will follow strict survey protocols, detailed below, and visualized by flowcharts in Appendix 3.

Step 1: Determine necessary survey effort level at each territory:

- If In-Use Nest present on previous visit, complete Steps 2–4, and then proceed to "In-Use Nest" protocol. This includes nests for which the previous status was "previously In-Use unknown" *(see description in "In-Use Nest" protocol),* until status is resolved.
- If an In-Use Nest in this territory was previously determined failed, do not survey.
- If early season surveys found no adults in the territory *(i.e., "Vacant Territory"),* or produced two or more separate sightings of two off-nest adults *(i.e., "Occupied Territory, no In-Use Nest"),* do not survey.

2374 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- If early season surveys found only one adult and no In-Use Nest, additional surveys may or may not be warranted. If all known nests were surveyed definitively on at least two separate visits, and at least one "Extended Search" was conducted of substrate within 250m of any adult sighting(s), no additional survey is necessary. Otherwise, follow Early Season protocol until these criteria are met or In-Use Nest is found.

Step 2: Record daily "Survey Start Time" when leaving English Village *(Ground/sUAS)* or runway *(UAS)*.

Step 3: Record individual "Territory Survey Start Time" when within 2-km buffer around known nests.

Step 4: Approach first nest viewing location of In-Use Nest and proceed to "In-Use Nest" protocol.

Step 5: Record "Territory Survey End Time" when leaving 2-km buffer around each territory, or when time expires *(NOTE: 3-hr territory limit begins upon entering 2km threshold but may expire during survey)*.

Step 6: Repeat Steps 2-5 until all territories allotted for survey in a given day are visited. Ground and sUAS may not survey territories allotted for other survey days to maintain separation of survey platforms.

Step 7: Record daily "Survey End Time" on return to English Village or runway.

"In-Use Nest" Protocol *(to be used with both "Early Season" and "Late Season" surveys)*: Surveyors will determine status of newly or previously found In-Use Nest by watching for up to 60 mins *(but ended sooner if definitive status is reached sooner, or maximum 4-hour territory time expires)*.

- For newly discovered "In-Use Nest", 60-minute clock begins when nest first verified used (e*.g., may exclude up to 30 mins of survey while still "unknown"*); for all others, time begins with arrival at view coordinate.
- If two adults seen on the nest, watch until confirmation of incubation/brooding, eggs, nestlings, fledglings, or *failure (proceed to those statuses below),* or list as "adults on nest-unknown" if status unresolved after 60 mins or when time expires.
- Incubation/brooding: if adult seen in incubating/brooding posture, record status and end nest survey.
- Egg(s): if egg(s) seen, record number, presence of adult(s), other circumstances, and end nest survey.
- Nestling(s): if nestling(s) seen after March 24, spend up to 60 mins attempting to count and age to nearest half-week. Surveys may be ended sooner without a count of nestlings when all-downy eaglet(s) *(<4 weeks)* seen. Note presence of adults, feeding events, etc. List as "unknown" age and/or count if unresolved after 60 mins or time expires *(or note if not attempted due to pre-March 24 date)*. If age is determined to be 7 weeks or older (80% fledge age), proceed to "fledgling" protocol below.

2375 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Fledgling(s): spend up to 60 mins attempting to determine total number of fledglings reaching at least 80% fledge age *(7 or more weeks).* Annual nest survey effort is complete when fledge age reached and confident fledgling count achieved *(may require subsequent week visit).*
- Failure: nest confirmed as empty of adults, eggs, or nestlings, after previous visit confirmed In-Use *(excluding "adults on nest-unknown"),* or status of previously confirmed In-Use Nest cannot be verified after two consecutive weeks of 60 min survey.
- Previously In-Use-unknown: status cannot be verified after 60 mins of watching, despite activity confirmed during a previous survey. Two consecutive nest surveys with this status results in assigning failure.

5.5 SAMPLING PROTOCOL

Laboratory samples were not collected during this demonstration. Field survey methods are addressed in section 5.4.

5.6 SAMPLING RESULTS

Laboratory samples were not assessed during this demonstration. Field survey results are addressed in section 6.0.

2376 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

6.0 PERFORMANCE ASSESSMENT

The demonstration team successfully completed two full seasons of eagle nest monitoring on DPG during 2019 and 2020 *(Table 4)*. However, eagle nesting initiation and success rates were very low across the entire Utah West Desert region during both years *(HawkWatch International 2019)*. Eagle nesting initiation is currently thought to be a function of available food supply, namely black-tailed jackrabbits for the West Desert population of golden eagles *(Steenhof et al. 1997)*. Jackrabbit populations in Utah are currently at a low in their population cycle, resulting in a few years of depressed golden eagle nest initiation and success *(HawkWatch International 2019)*. Eagle nesting success may begin to trend upwards as soon as next year *(2021)* as rabbit populations rebound *(Bedrosian et al. 2017)*. It may be that better eagle nesting success during monitoring would allow for a larger dataset and more robust conclusions regarding the abilities of each monitoring platform.

6.1 STATISTICAL ANALYSIS

As a result of the low nesting initiation and success rates on DPG during both monitoring seasons, the demonstration team was not able to collect enough independent data points to support a robust mixed effect regression model to assess platform success as we had proposed. The large number of variables involved in our proposed model demand a large set of independent nest observations, and a large number of replications of those observations. We only observed two in-use nests in 2019, and 3 in 2020 *(although only one nest in 2020 survived to fledging age)*. Instead, the DPG Team developed a simplified version of the proposed model focusing on general nest observations and status assessment. Survey platform was treated as a fixed effect with the binary response variable being correct or incorrect weekly nest status classification within each territory based on the "true" weekly status. Territory, survey week, and period *(early/late)* were treated as random effects. Mixed effect modeling allowed us to assess whether the survey platform influenced the odds of correctly classifying weekly statuses, outside the random effects of time and territory. In addition, the DPG Team created a logistic regression model to assess the effects of survey platform on the amount of time required to determine nest status. Survey platform was treated as a fixed effect with the number of minutes required to determine each nest status as the response. We included territory, survey week, and nesting period as additional variables. We ran two separate runs of both models for each year, as the differences in sUAS platforms greatly affected the results from year to year.

The initial proposal was to compare military UAS platforms to the sUAS and ground observer teams directly. However, it was determined in the first season of operation *(2019)* that flight schedules for the military UAS platforms were too sporadic to support regular nest monitoring. The military UAS were only able to monitor nests on an as-available basis, and other missions, weather, and maintenance concerns frequently bumped nest observations off the schedule. In addition, the COVID-19 crisis in 2020 resulted in the UAS observer being barred from conducting nest observations within the UAS control box due to health and safety concerns. Due to a lack of repeated observations on the same scale as the ground observer and sUAS, the military UAS platform was not included in the comparison models.

2378 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

6.2 TIME TO EARLY SEASON OCCUPANCY STATUS

The ground observer and the sUAS took roughly the same amount of time to determine early season territory occupancy each year, even with the change in sUAS platform in 2020. The ground observer took a mean time of 111 minutes to determine occupancy in 2019 (SD = +-64) and 108 minutes in 2020 (SD = +- 64). The sUAS observer took a mean time of 108 minutes in 2019 (SD = +- 54) and 91 minutes in 2020 (SD = +- 50). The UAS took vastly less time to make a territory determination in 2019, although this is mostly due to the limited available flight time the platform had to work within. The UAS platform was rarely able to make definitive determinations within the given time allowed and was removed from the comparison. Most of the time required by both the sUAS and ground observer was taken by drive time between nests in a territory *(Figure 7).*

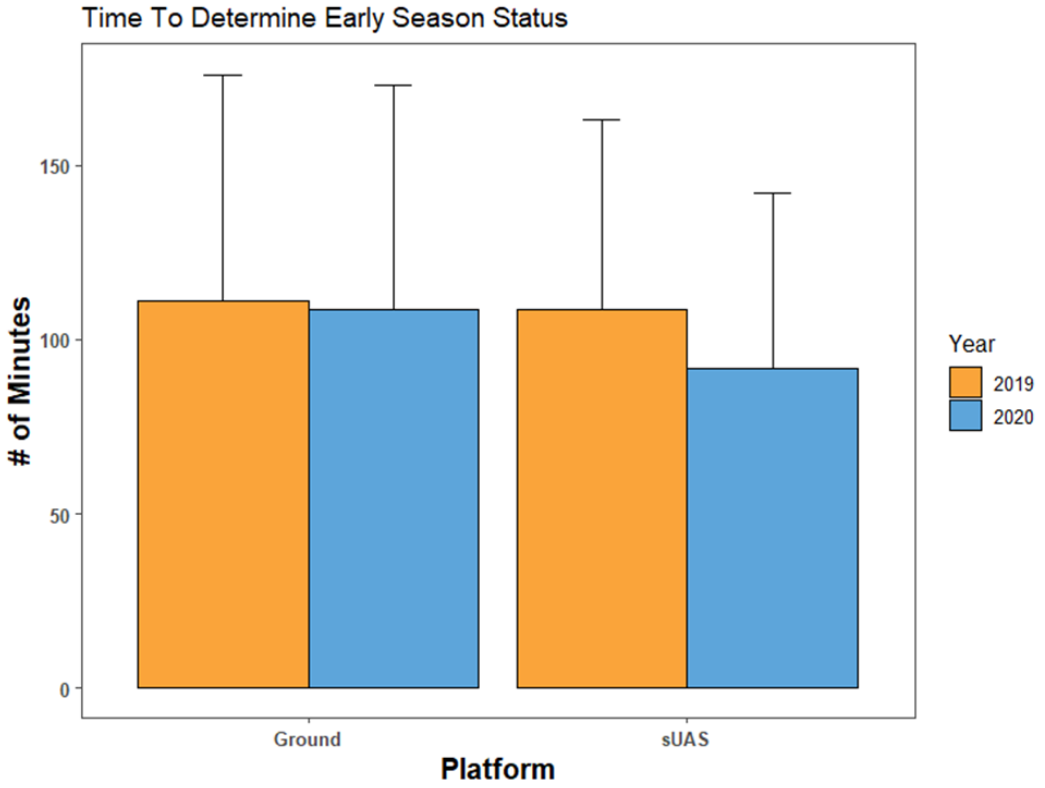

Figure 7. Chart Showing the Mean Time in Minutes (+SD) each Platform Required to Determine the Early Season Occupancy of a Territory.

6.3 NUMBER OF IN-USE NESTS IDENTIFIED

Both the ground observer and the sUAS found the same number of in-use nests each nesting season, while the UAS was unable to locate one of the in-use nests in 2019 *(the UAS was forced to cease operations before in-use nesting in 2020 due to COVID-19).* An interesting point to be considered is that in 2020, there were actually 3 in-use nests. The ground observer located one in-use nest that the sUAS was unable to observe due to territorial aggression against the platform by the eagle pair, while the sUAS located an in-use nest that the ground observer was unable to survey due to lack of ground access in an Impact Area. This illustrates the fact that both survey methods have strengths and weaknesses that the other can supplement *(Figure 8).*

2379 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

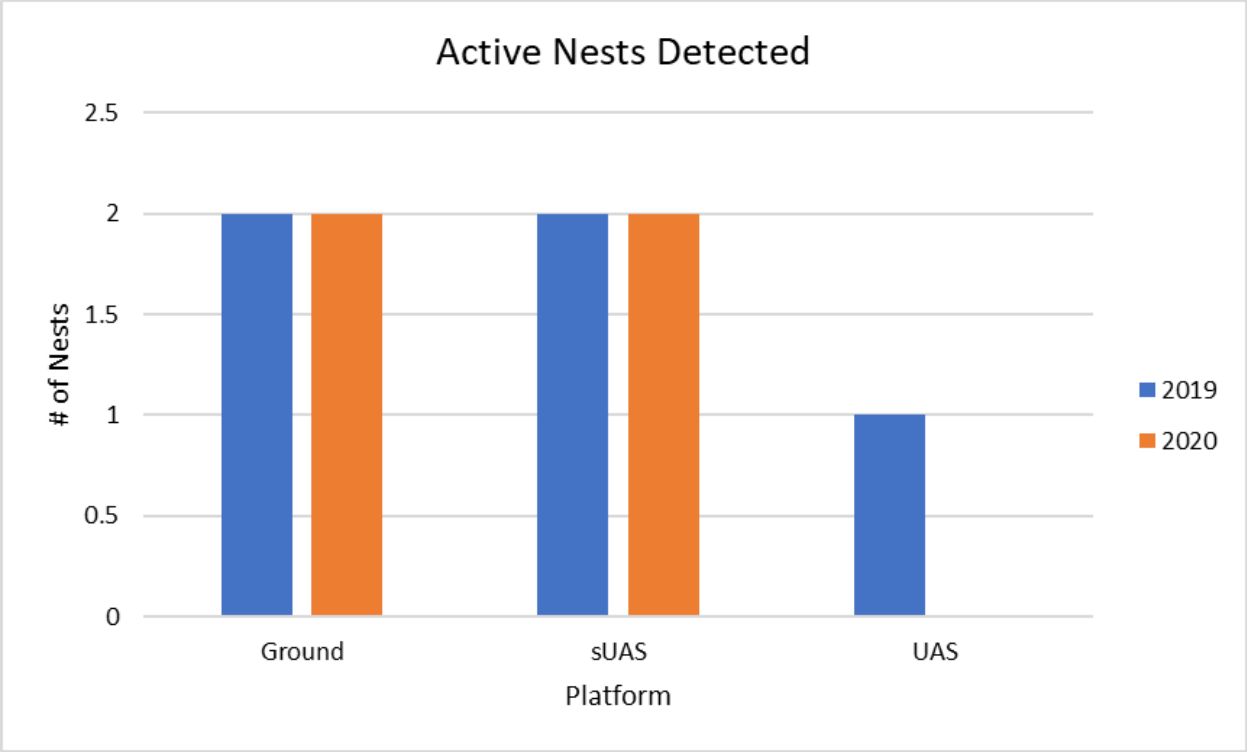

Figure 8. Chart Showing the Number of In-use Nests Each Platform Identified During Each Breeding Season.

6.4 DATE OF IN-USE NEST IDENTIFICATION

The sUAS platform was roughly equal with the ground observer at detecting in-use nests in 2019. The sUAS platform was able to survey almost every known nest in each assigned territory each week, making it more likely for the platform to detect an incubating eagle within a week of nesting initiation. The ground observer, on the other hand, was forced to rotate which nests were surveyed during each visit due to long hikes over rough terrain. The 2019 UAS was typically not able to identify nest activity due to the low resolution of its payload and the lack of precise nest metadata provided to its pilots and was not compared. In 2020 the sUAS was again roughly equal to the gound observer in nest detection time, despite the sUAS's drop in payload resolution. This indicates that the advantage of visiting more nests outweighed the disadvantage of poor payload resolution. In 2020, the UAS platform was forced to cease surveys before nests became in-use, removing it from this comparison *(Figure 9)*.

2380 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

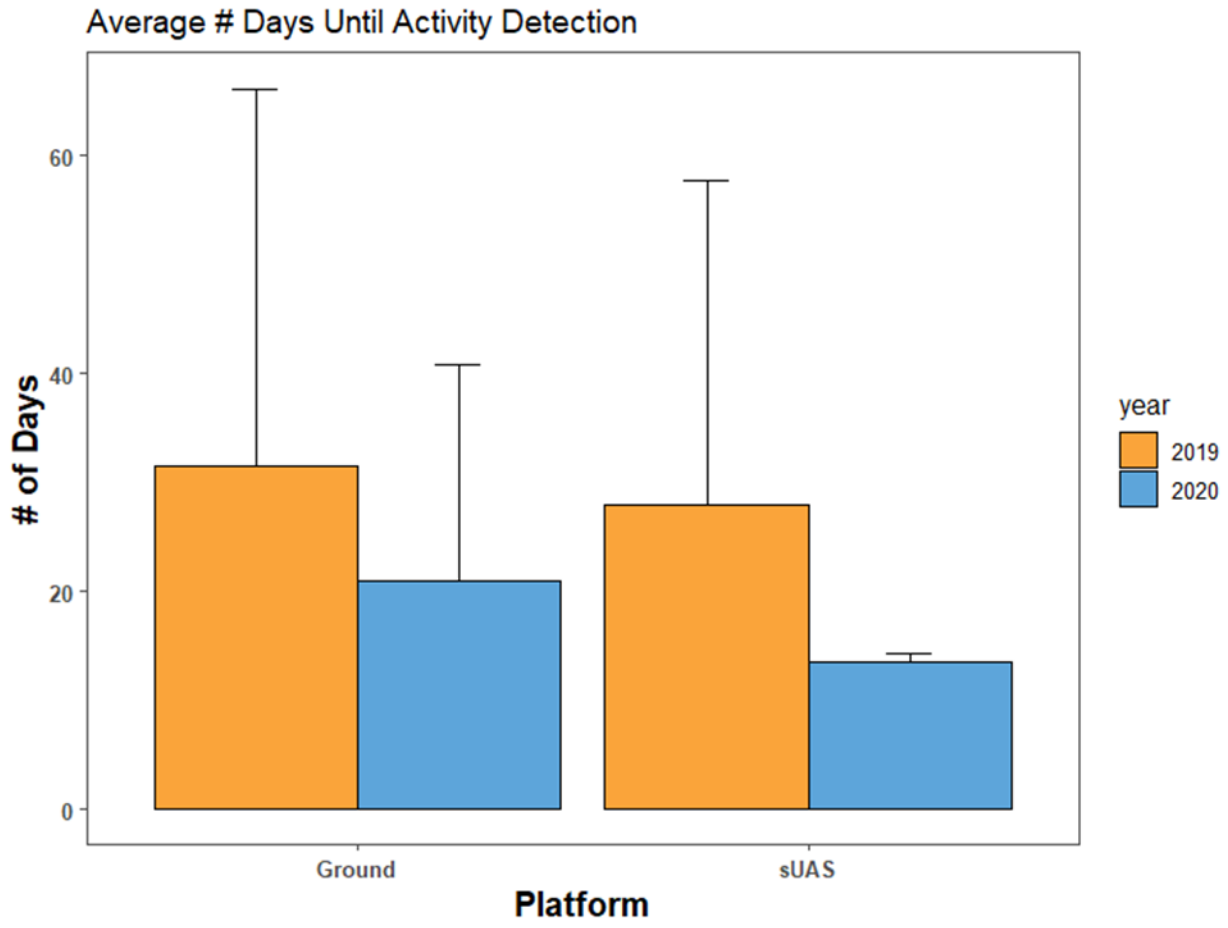

Figure 9. Chart Showing the Mean Number of Days (+SD) from Nest Initiation to Activity Detection by Each Platform.

6.5 DATE OF NEST FAILURE OR FLEDGE IDENTIFICATION

In 2019, the ground observer and sUAS platforms very nearly tied for speed at detecting nest failure or fledge. Both had sufficient quality optics and visitation rates to detect the lack of chicks in a nest almost immediately. The UAS was not compared due to lack of data. By contrast, the ground observer was much faster to detect nest failure or fledge in 2020 than the sUAS. The sUAS's loss of payload resolution made it difficult for the platform to identify the presence or absence of small chicks in a nest. Again, the UAS was forced to cease surveys before nests became in-use, removing it from this comparison *(Figure 10)*.

2381 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

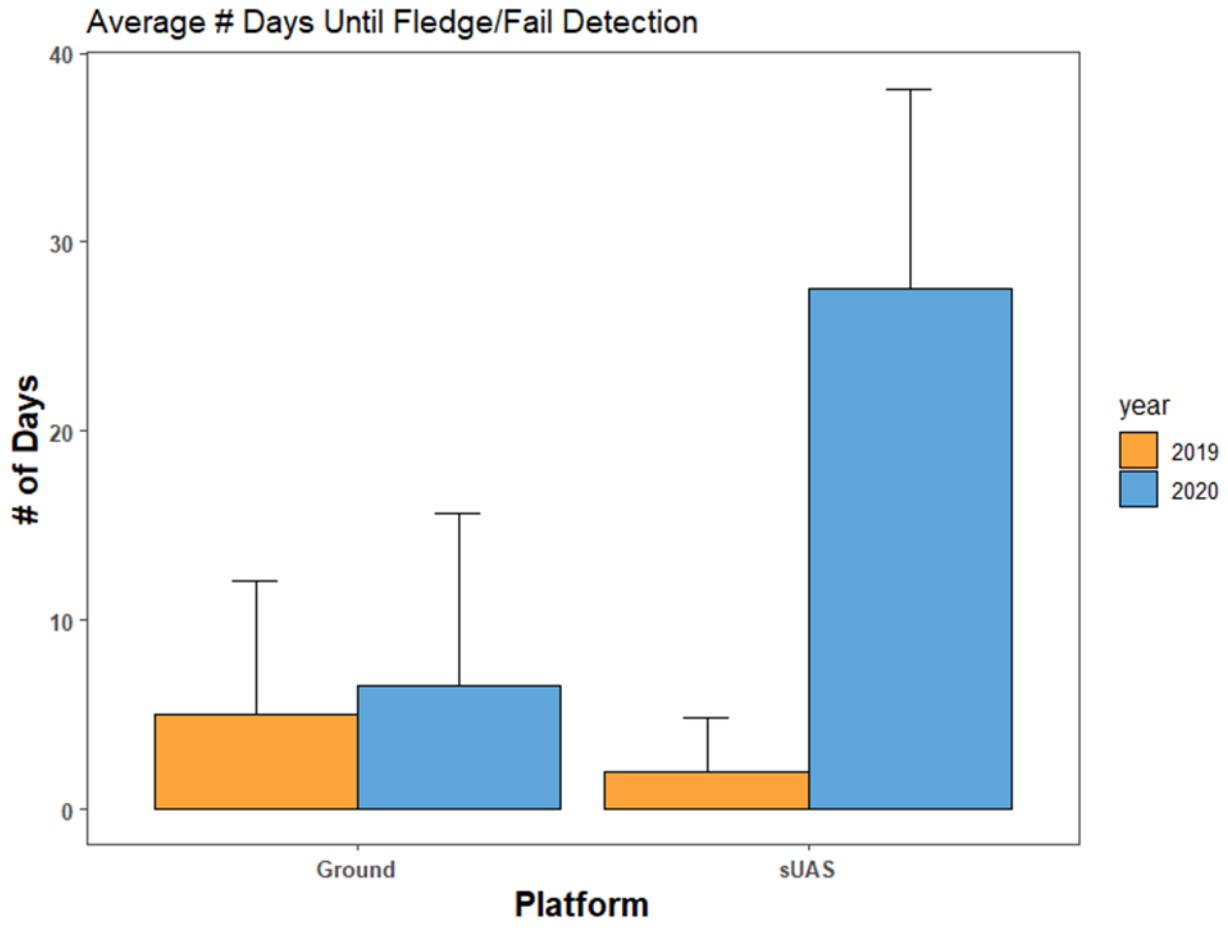

Figure 10. Chart Showing the Mean Number of Days (+SD) from Nest Failure or Fledge to Detection by Each Platform.

Error bars represent standard deviation.

6.6 TIME TO NEST STATUS UPDATE

The following logistic regression models illustrate the differences in nest observation efficiency both between platforms and between years. In 2019, the sUAS displayed a clear efficiency advantage over the ground observer, requiring much less observation time to make a nest status determination, especially in the early nesting season. This is because of the sUAS's ability to view directly into a nest bowl, eliminating the need to wait for a possible incubating eagle to stand or stretch in order to come into view from the ground. As the nesting season went on and chicks got larger, they were easier to see from below, decreasing the advantage of the sUAS. In 2020, the sUAS retained a small advantage over the ground observer, but the poor resolution of the payload meant that the platform had to observe each nest for much longer in order to determine if an object perceived to be in the nest was actually an eagle or if it was simply a pixilation artifact. In addition, the ground observer in 2020 took more time on average as the season went on, mostly due to the fact that one of the in-use nests was located in a high, partially obscured cliff cavity, preventing easy observation at any time.

2382 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

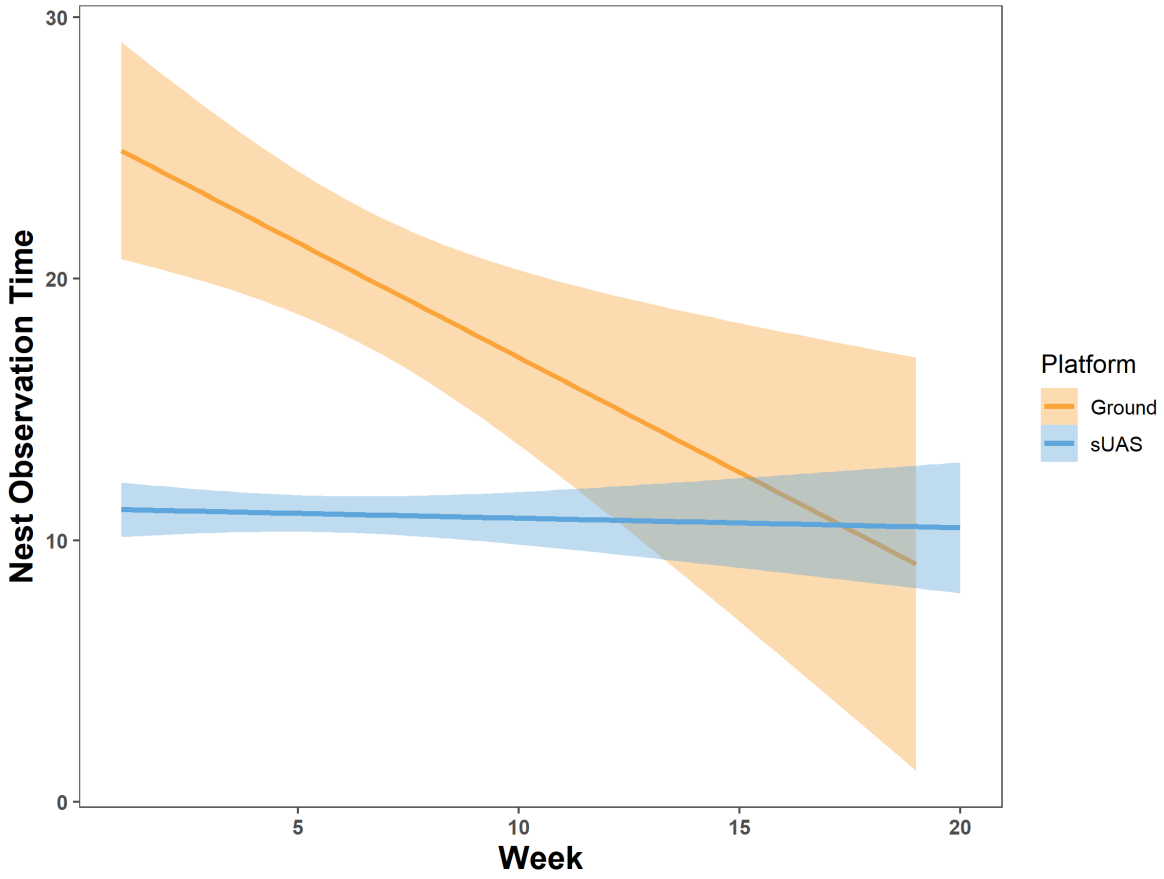

Figure 11. Comparison of the Efficiency of a Ground Observer in Minutes (± 95% Confidence Intervals) vs an sUAS at Determining Any Given Nest's Status During 2019.
The sUAS took vastly less time to determine status during early season, while the ground observer gained efficiency as unused nests were eliminated from the survey round.

2383 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

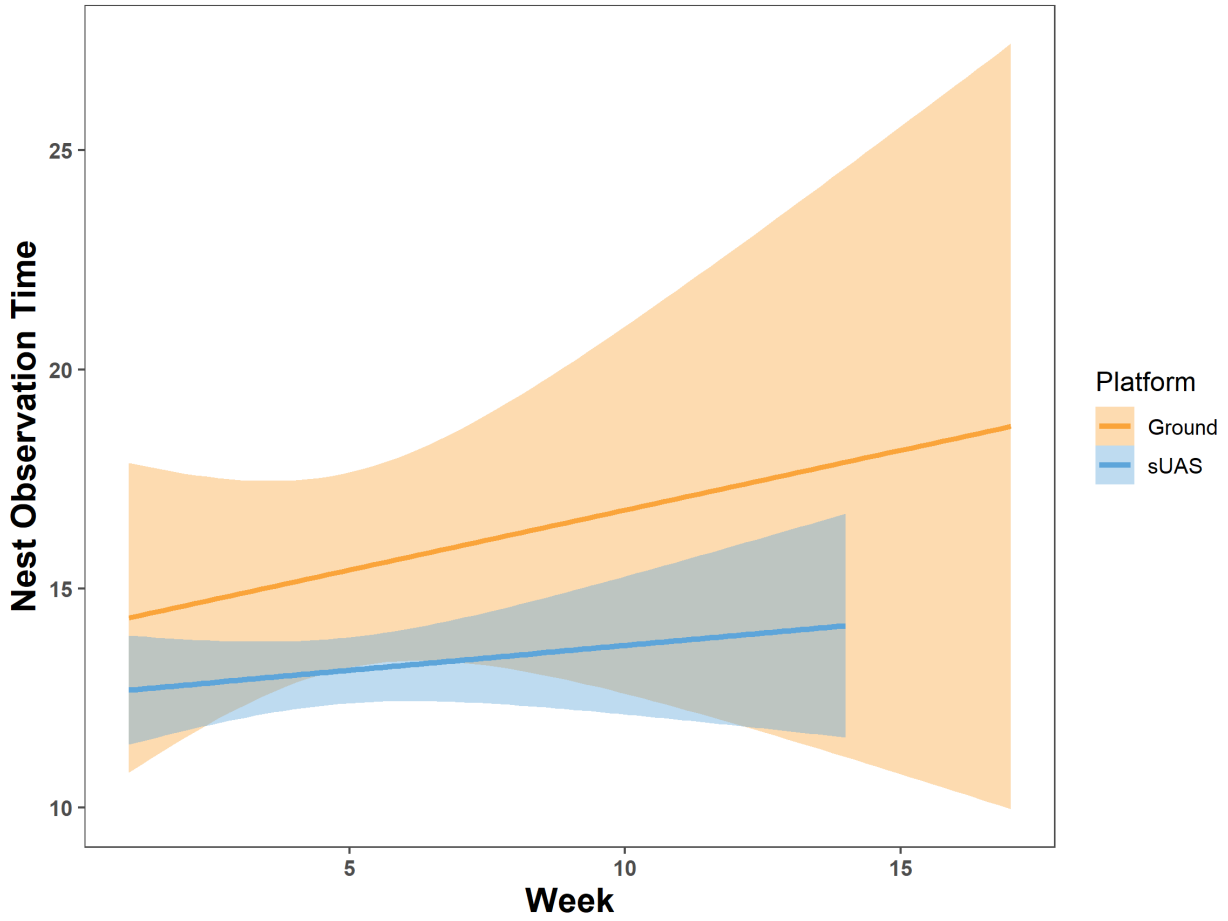

Figure 12. Comparison of the Efficiency of a Ground Observer in Minutes (± 95% Confidence Intervals) vs an sUAS at Determining Any Given Nest's Status During 2020.
The sUAS took less time to determine status on average. The sUAS's efficiency advantage was much less pronounced than during 2019.

6.7 NUMBER OF NEW NESTS FOUND

In both 2019 and 2020, the sUAS outcompeted the ground observer and the UAS at finding previously undescribed nests. The sUAS had the advantage of covering a great deal of territory quickly, while also taking photos and video of terrain to be later analyzed for potential nests. The ground observer was unable to visit as much of each territory and had to focus on observing already known nests, preventing the observer from spending much time scanning for new nests. The UAS was unsuited to locating new nests due to the complications of approach angle and low payload resolution in 2019 and did not have enough survey time to draw a comparison in 2020 *(Figure 13)*.

2384 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

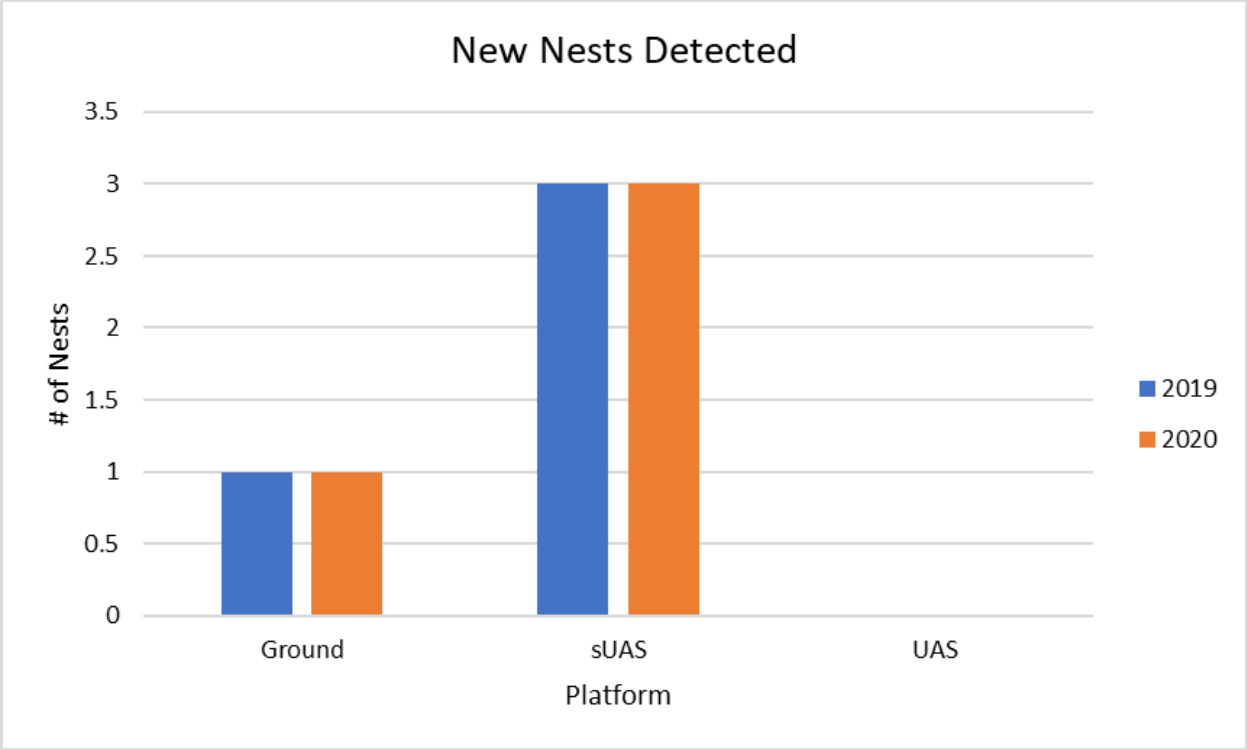

Figure 13. Chart Showing the Number of New Nests Each Platform Located During Each Season.

6.8 HYPOTHETICAL MISSION IMPACT IN DAYS

The hypothetical mission impact of nest area closures and openings is a measure of the precision of each platform in detecting nest status changes. Ideally, an in-use nest will be detected, and an area closure enacted immediately *(within one week or survey period)* upon the start of incubation, and the area opened again immediately upon the failure or fledge of the nest. This minimizes potential mission impacts of unnecessary range closures as well as protecting the nest against potential disturbance *(Figure 14)*.

In 2019, both the ground observer and sUAS platform were slow to detect the activity of RN315, leaving it unprotected for several weeks, although the sUAS was one week quicker in detecting the nest's activity. In addition, the ground observer designated RN315 as fledged prematurely by one week. This resulted in the sUAS being cumulatively more precise in designating range closures in 2019 than the ground observer.

In 2020, the data is complicated by the fact that both the ground observer and the sUAS monitored nests that the other platform was not capable of reaching, leaving only one nest for direct comparison. The ground observer was slow to detect the activity of RN248A by several weeks but caught the fledge of the nest immediately. The rough terrain and lack of road access in RN248A's territory required the ground observer to ration which nests received a survey visit each week, which resulted in the in-use nest going undetected for several weeks. The sUAS detected the activity of RN029 immediately but was slow to confirm the failure of the nest by several weeks.

2385 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The low resolution of the platform payload in 2020 made it much more difficult to identify the presence or absence of young chicks from the nest bowl than the presence or absence of an incubating adult. Both platforms were equally precise at determining the status of RN321.

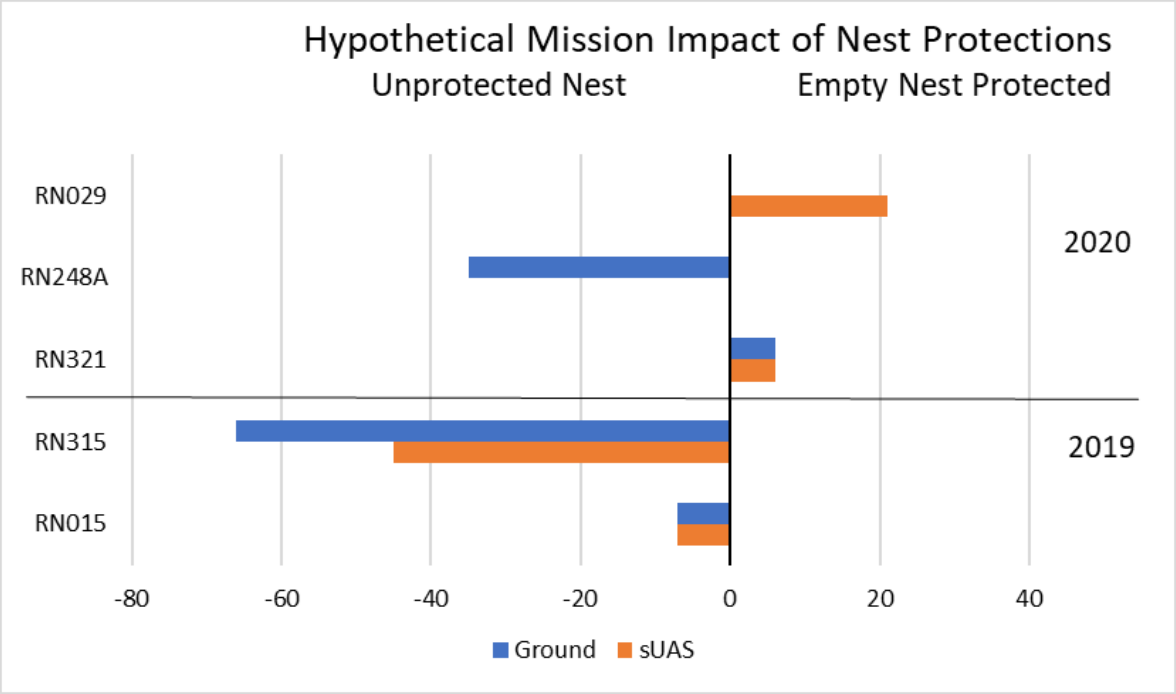

Figure 14. Chart Showing the Hypothetical Impact of Nest Area Closures/Openings by Platform and Year.

The 0 line represents no deviation from actual nest use, i.e., the desired perfect protection.

6.9 QUALITY OF PHOTO/VIDEO DOCUMENTATION

The DPG Team conducted a qualitative evaluation of how well each platform was able to document nest status in both 2019 and 2020. In 2019, the sUAS platform delivered high resolution video and photo documentation of all nests viewed, as well as footage of the surrounding cliffs for the team to search for previously unknown nests. The photo/video documentation allowed the data managers to confirm nest status before putting range closures in place. By contrast, the UAS platform in 2019 was equipped with a low-resolution payload that hampered the observer's ability to identify nests with confidence. The UAS's thermal imaging capability did allow the observer to spot chicks in in-use nests, however. In 2020, the imaging capabilities of the sUAS and UAS platforms were reversed. The replacement sUAS platform had a downgraded payload resolution due to downlink limitations. In addition, it did not have onboard data recording capabilities; the observation team had to record footage from the ground station, and as a result encountered significant issues with poor reception and signal corruption. These limitations resulted in the sUAS team requiring more time on site to determine nest status, and in many cases prevented the team from calling a certain nest status at all. On the other hand, the UAS platform received a significant upgrade to its payload systems, allowing for HD image recording. Unfortunately, the UAS team was forced to cease survey operations after only 2 weeks of monitoring due to the COVID-19 crisis, and the observation team was unable to obtain enough data to present a significant image comparison.

6.10 ADDITIONAL METRICS FOR SUCCESS

The results of the mixed-effect logistic regression models indicate that the ground observer and sUAS platform had essentially equally *(high)* accuracy in determining the status of any given nest in 2019. Both platforms were more than 85% likely to determine nest status accurately and confidently in the early season, growing to more than 95% accurate in the late season. This can be attributed to the experience and skill of the ground observer, as well as the ability of the sUAS platform to take high quality documentation photos and video for review. In 2020, the sUAS platform suffered greatly from the drop in payload resolution. It began strongly and was still confidently able to determine when nests were not in-use. However, it struggled to accurately identify when nests were in-use and to determine the difference between an incubating nest and a nest with chicks. The ground observer, on the other hand, displayed almost the same results as in 2019 *(Figures 19 & 20)*.

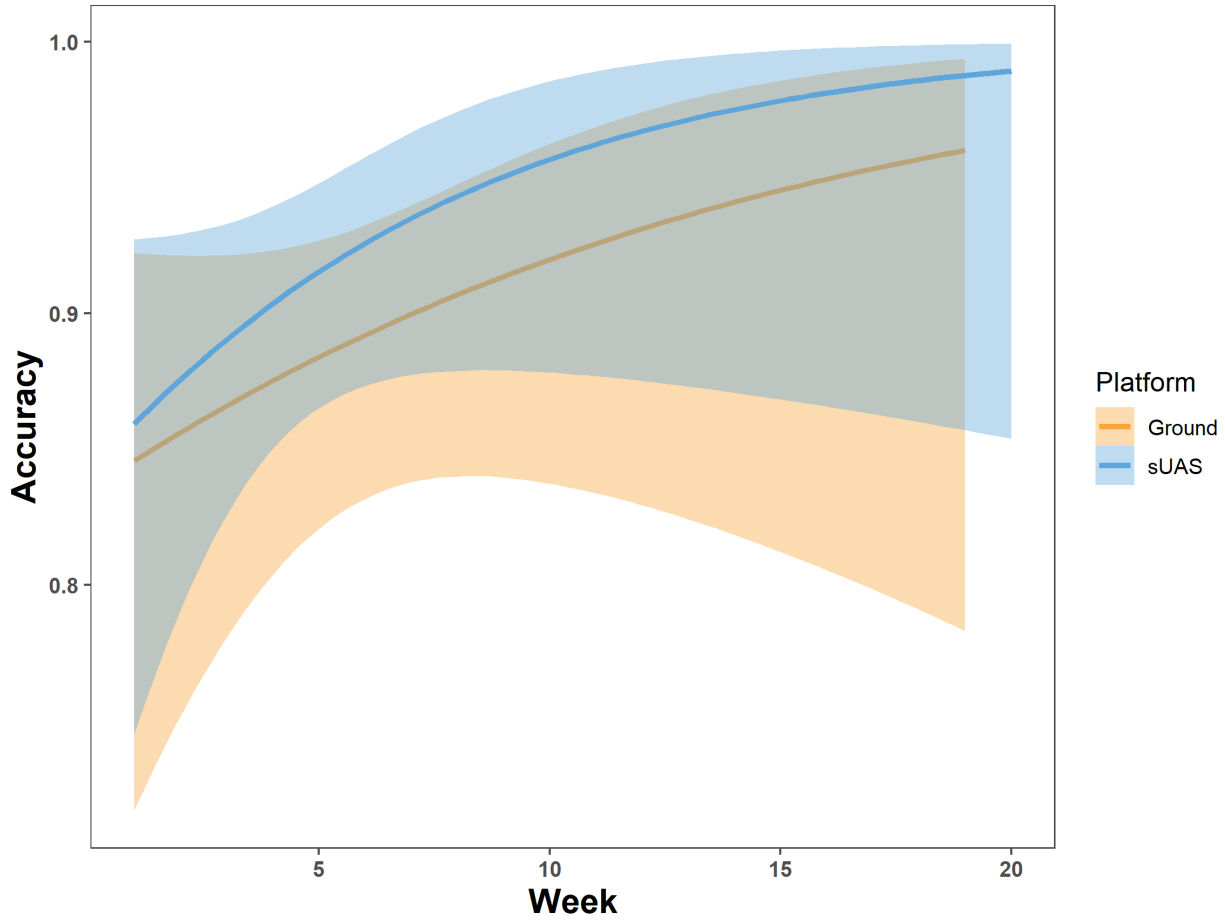

Figure 19. Comparison of the Accuracy of a Ground Observer (± 95% Confidence Intervals) vs an sUAS at Determining Any Given Nest's Status During 2019

Both platforms gained accuracy as the season went on, roughly equal in accuracy.

2389 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

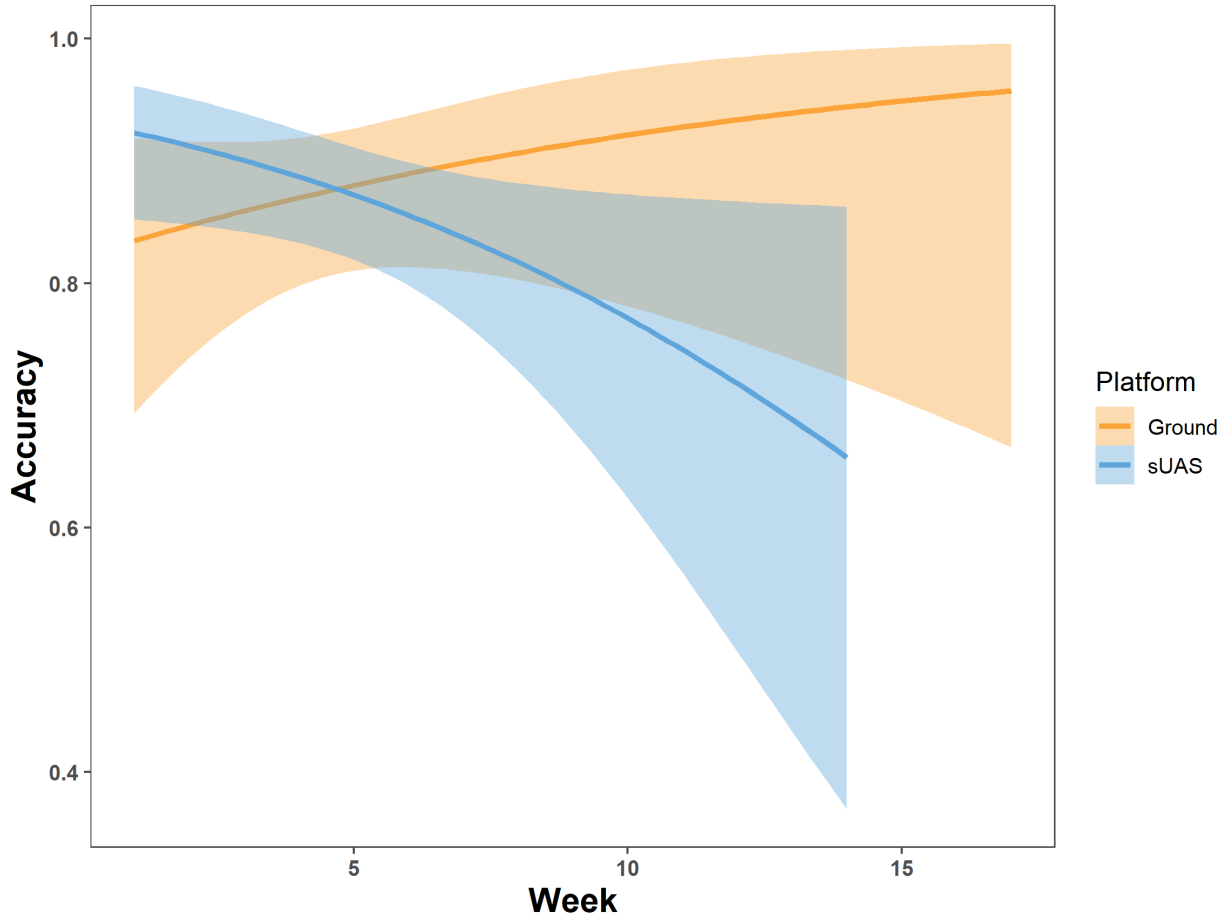

Figure 20. Comparison of the Accuracy of a Ground Observer (± 95% Confidence Intervals) vs an sUAS at Determining Any Given Nest's Status During 2020.

The ground observer gained accuracy during the season, mirroring 2019, while the sUAS lost accuracy. This represents the challenges of identifying an in-use nest's status with a low-resolution payload.

When determining which platform is most efficient and cost-effective, it is important to take total territory coverage into account, especially in the early nesting season when looking to identify in-use nests. The sUAS platform was able to survey approximately twice as many nests each week than the ground observer in both 2019 and 2020. This grants the sUAS more confidence in accurately calling the occupancy status of early season territories, as well as giving it an advantage in locating in-use nests promptly. This played out in 2019 as the sUAS located one in-use nest a full week before the ground observer. The ground observer had to rotate which nests to observe each week due to time pressure and the lengthy hikes needed to cover some territories. By being unable to cover all known nests each week, the ground observer was slower to identify an in-use nest, leaving it potentially vulnerable to disturbance *(Figure 21)*.

2390 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

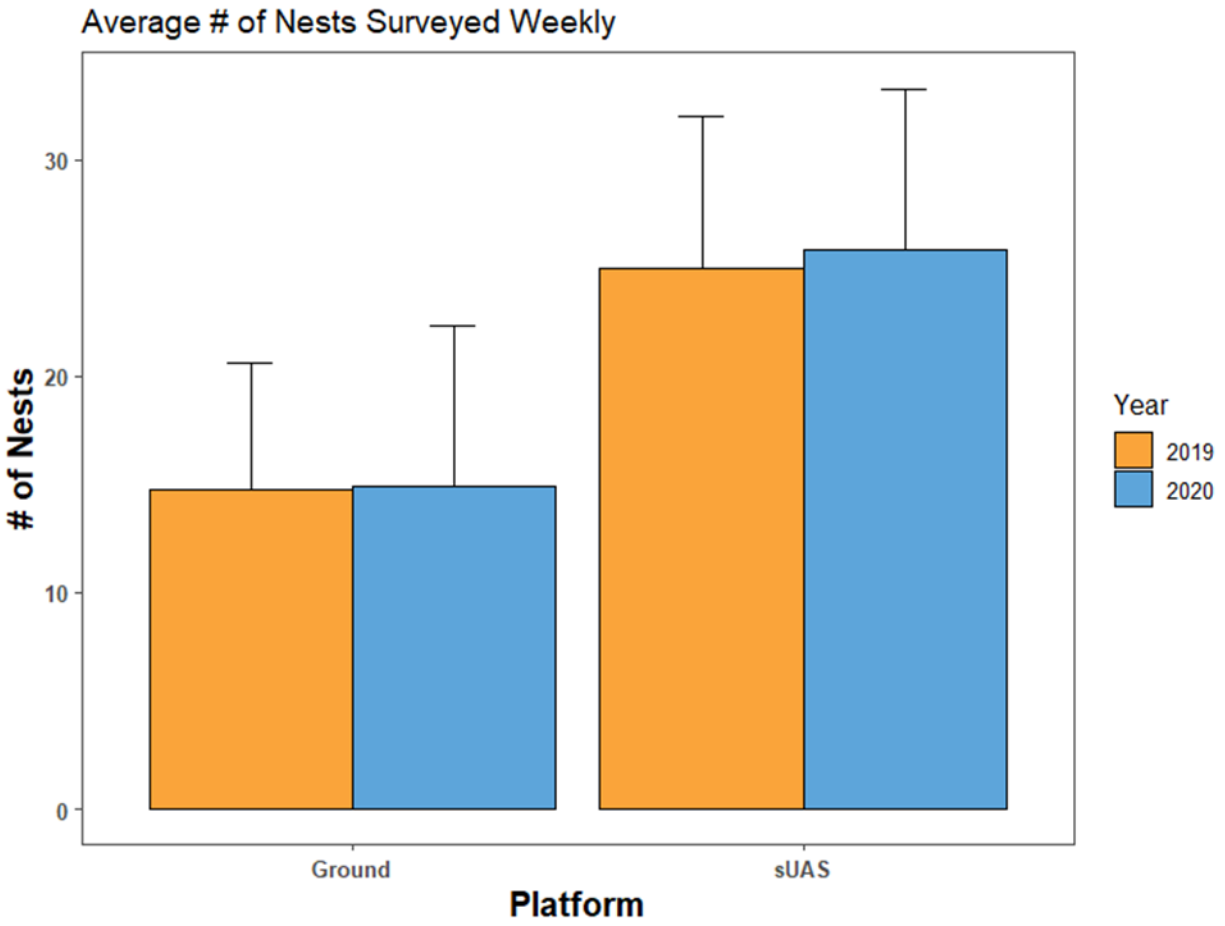

Figure 21. Chart Showing the Mean Number of Nests (+SD) Surveyed Each Week During the Early Season.

There is high variation from week to week depending on which territories were assigned for survey, but the sUAS consistently outperformed the ground observer over the same territory assignments.

2391 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

7.0 COST ASSESSMENT

The cost assessment included actual costs of both the sUAS and the on-the-ground observer. However, the actual costs are skewed based on a few circumstances that were out of the ordinary for this project. Just as this demonstration was beginning, the DoD memo was released banning COTS sUAS. The cost of the modified COTS sUAS included non-recurring engineering costs that would not have been included in a COTS sUAS. The changes in policy also required assistance from a Government organization to prepare and obtain a waiver for the project and provide direct oversight of the flights.

7.1 COST MODEL

The tables below break out the costs for each of the monitoring methods for comparison. Due to the significant differences between the two sUAS these were also broken out for comparison. Table 5 provides the costs for year one using the DJI Matrice and Table 6 provides that costs for year two using the E900. Both tables show the cost of Government support for waiver preparation and sponsor/oversight of flights. This cost should not necessarily be considered for future projects.

Table 5. One Year Cost Model for an sUAS.

Cost Element	Data Tracked During the Demonstration	Estimated Costs
Platform	Purchase of sUAS *Modified commercial sUAS *(DJI Matrice)*	$18,139
Payload	Purchase of camera	NA- Integrated into platform
Batteries/Chargers	Purchase of extra batteries/chargers	$1,528
Binoculars/Scope	Not Applicable for sUAS	NA
Transportation	Mileage to-from observation locations	$3,000
Maintenance/Repair	Purchase of repair kit and replacement parts	$256
Monitoring Labor	Team of three	$55,346
Waiver Development *(Contractor)*	Development of waiver request memo and supporting documentation	$7,000
Govt. waiver prep and sponsor/training/oversight of flights	Cost of Govt. support for waiver	$79,557
Total		$164,826

Table 6. One Year Cost Model for an sUAS

Cost Element	Data Tracked During the Demonstration	Estimated Costs
Platform	Purchase of sUAS *Modified commercial sUAS *(E900)*	$5,500
Payload	Purchase of camera	$5,895
Batteries/Chargers	Purchase of extra batteries/chargers	$1,651
Binoculars/Scope	Not Applicable for sUAS	NA
Transportation	Mileage to-from launch locations	$3,000
Maintenance/Repair	Purchase of repair kit and replacement parts	$893
Monitoring Labor	Team of three	$48,840
Waiver Development *(Contractor)*	Development of waiver request memo and supporting documentation	$7,000
Govt. waiver prep and sponsor/ training/oversight of flights	Cost of Govt. support for waiver	$61,249
Total		$134,028

Table 7 below shows the costs for the military UAS. Because the military UAS was used on an as available basis the costs of the platform/payload were not applicable. Only the cost associated with the biologist that sat with the UAS pilots was calculated. The cost of a military UAS not be cost-effective for natural resource monitoring alone. However, if an installation has a UAS program and the platform can be made available as part of the pilot training program, it is a useful tool to have.

Table 7. One Year Cost Model for an UAS

Cost Element	Data Tracked During the Demonstration	Estimated Costs

Table 8 below provides a detail on the costs for on the ground monitoring. This was performed by one biologist for the two-year study.

Table 8. One Year? Cost Model for On-the-Ground Monitor

Cost Element	Data Tracked During the Demonstration	Estimated Costs
Platform	Not Tracked	NA
Payload	Not Tracked	NA
Batteries/Chargers	Not Tracked	NA
Binoculars/Scope	Approximate Cost	$2,000
Transportation	To and from observation locations	$3,130
Maintenance/Repair	Not Tracked	NA
Monitoring Labor	One Biologist	$14,715
Waiver Development *(Contractor)*	Not Tracked	NA
Govt. waiver prep and sponsor/ training/oversight of flights	Not Tracked	NA
Total		$19,845

Table 9 below shows the cost of using helicopters for monitoring. These costs are based on historical costs since helicopters were not used during the two-year study.

Table 9. One Year? Cost Model for a Helicopter

Cost Element	Data Tracked During the Demonstration	Estimated Costs
Platform	Per hour cost of $1,500 for 36 days (4 hours/ day)	$216,000
Payload	Not Tracked	NA
Batteries/Chargers	Not Tracked	NA
Binoculars/Scope	Approximate Cost	$2,000
Transportation	Not Tracked	NA
Maintenance/Repair	Not Tracked	NA
Monitoring Labor	One Biologist	$8,640
Waiver Development *(Contractor)*	Not Tracked	NA
Govt. waiver prep and sponsor/ training/oversight of flights	Not Tracked	NA
Total		$226,640

2394 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The two tables below provide a side-by-side comparison of the two sUAS, UAS, on-the-ground monitor and helicopter. Table 10 includes the cost of Government support to prepare, obtain a waiver for the sUAS and monitor flights, while Table 11 removes those costs. Due to the unique circumstances faced during this demonstration, it is assumed that the additional cost for Government support for waiver and oversight would not be necessary for future projects.

Table 10. Cost Comparison of Methods with Government Support for Waiver

Cost Elements	sUAS-DJI Matrice	sUAS- E900	UAS	On-The-Ground	Helicopter

2395 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Cost Elements:

sUAS Platform: The sUAS platform is a primary cost. The platform must be able to meet, in this case, DoD Army cybersecurity and procurement requirements while also being able to accommodate the necessary payload. Performance, durability, and flight time are all important factors when selecting a platform.

Costs for the sUAS DJI Matrice 600: This is based on actual costs of the two DJI Matrice acquired from the Government. The DJI Matrice 600 were COTs that had been modified to use a U.S. developed software for control. This modification increased the cost of the sUAS.

Costs for the sUAS E900: This was an estimated cost provided from the Government. The E900 used in the second year were loaned to the program. The E900s used in this project could be considered developmental. The payload was integrated into the system and was not part of the original system.

sUAS Payload: The sUAS payload includes the camera and/or sensors. The payload can be a significant cost depending upon the requirement and whether or not it has been integrated into the platform. The payload weight will also need to be considered when selecting an sUAS platform.

Batteries/Chargers: Batteries are critical for the operation of the sUAS and are a significant cost. Back up batteries are necessary to ensure flights can continue without downtime. Charging infrastructure for the batteries was also a consideration. Because the sUAS are used in remote locations, it is necessary to have portable charging for the batteries.

Binoculars/Scopes: High quality binoculars and scopes are necessary for on-the-ground and helicopter monitors.

Transportation: Both sUAS and on-the ground monitoring requires transportation from a starting location to the monitoring or launch location.

Maintenance/Repair: Although little maintenance or repair was performed during this demonstration, it is important to consider when implementing a program. Common maintenance/repairs include battery charging, loose bolts/fittings, broken rotors, landing gear, etc. Each platform was only operated for a few months in each year. Industry data suggests the life cycle of the typical sUAS to be approximately 200 flights.

Monitoring Personnel: Personnel for the sUAS consisting of a pilot, an operator, a biologist, and observer. The observer was a person associated with the waiver who ensured that all requirements were being met. However, based on experience, the four people could be reduced to two *(pilot/biologist)*.

Waiver Development *(Contractor):* The Exemption to Policy (ETP) waiver process includes the technical documentation of the sUAS to obtain an Airworthiness Release (AWR). Once the AWR is in place, the development and approval of standard operating procedures, System Safety Management Plan, risk acceptance memos, and the formal ETP memo signed by a senior official may be prepared.

2396 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The preparation of this material, the submission through a SIPR account, discussions/clarifications from the Army CIO, staffing of memos for signature, all take time and have an associated cost. The process to obtain an ETP changed three times from 2018 to 2020.

Access to Installation and Logistics: This cost is associated with obtaining base access and coordination with range control and flight control.

Government Waiver Preparation and Sponsorship/Training/Oversight of Flights: This cost may be eliminated or significantly reduced in the future. During this demonstration, it became necessary to engage with another Government organization to sponsor the waiver and to support its development. In addition, this organization was able to provide a modified sUAS that was capable of meeting DoD cyber requirements. Because they were the sponsor of the waiver, they were on-site to provide training on the sUAS and weekly flights.

7.2 COST DRIVERS

The most significant cost driver is DoD Army sUAS policy. The platform/payload must meet Department of Army cyber security requirements. Each platform must undergo an evaluation and provide an Exemption to Policy (Waiver) to operate in restricted airspace. The cost associated with obtaining an ETP includes labor to develop the ETP application package *(Standard Operating Procedures, System Safety Management Plan, and Memos),* upload through SIPR, and track through the system. The waivers are only for six months. In addition, each sUAS must have an Airworthiness Release.

The prohibition on foreign made sUAS impacts costs because the U.S. market is still developing and has not yet produced a cost competitive commercial sUAS to compete with foreign made sUAS. As the U.S. market matures and purchases increase, this will begin to bring the costs down.

7.3 COST ANALYSIS AND COMPARISON

Costs are based on golden eagle monitoring on a MRTBF with vast distances between nests and rugged terrain. Breeding season begins in February and goes through June, allowing for a range of temperatures and weather conditions.

The cost comparison assumes that both the sUAS and on-the-ground monitoring start and return from the same location. The time to survey nests and return to the starting location was recorded.

Industry data on life expectancy of an sUAS is approximately 200 flights. When first envisioning this project, it was thought that the sUAS would be most cost-effective and could replace the current approach of on-the-ground monitoring. The results from the demonstration show that the use of an sUAS is a good tool to have available but may not be able to cost-effectively replace on-the-ground monitoring. For instances where the nests are too high or distances too long or rugged, sUAS are a good tool. As the cost of the sUAS system is reduced and the policy surrounding flying the sUAS in DoD airspace is streamlined or eliminated, it may become cost-effective compared to on-the-ground monitoring. The sUAS is more expensive than on-the-ground monitoring, however, the sUAS provides benefits over that of the on-the-ground monitor such as photos which can be used to study and accurately age the chicks. The sUAS can also cover more territory than an on-the-ground monitor and access nests that are too high or at a difficult angle to see from the ground.

2397 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In addition, some of the costs associated with this demonstration can be reduced or eliminated. For instance, a three-person team was used to monitor eagles *(the pilot in charge, operator, and observer).* In the future, this team could be reduced to a two-person team. In addition, the Government sponsor of the waiver observed weekly flights which required labor and travel. Due to COVID-19 in the 2020 season, the Government sponsor was able to designate a local Government Point of Contact (POC) to provide oversight which reduced costs. The use of sUAS compared to a helicopter is cost competitive.

2398 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

8.0 IMPLEMENTATION ISSUES

8.1 SUAS IMPLEMENTATION

A major implementation issue with the use of sUAS in DoD airspace involves obtaining an Airworthiness Release (AWR) and Exemption to Policy (ETP). This policy seeks to prevent the use of foreign made sUAS based on cybersecurity vulnerabilities. Both approvals take time to develop, review, and obtain approval. Under the 2019 DoD Army policy, a modified DJI Matrice 600 was used to monitor golden eagles after obtaining an ETP. However, because of the FY 2020 NDAA, Section 848 Prohibition on Operation or Procurement of Foreign Made Unmanned Aircraft Systems, the procurement or use of Chinese made sUAS was prohibited. This led to the use of a different sUAS platform. Each change of platform requires a new AWR and ETP. The ETP can only be granted for six months at a time and the time to obtain an approval may take 45-60 days minimum.

To obtain an Airworthiness Release, a Standard Operating Procedure, System Safety Management Plan, Material Risk Acceptance Memo, and Operational Risk Acceptance Memo, must be developed and submitted to the Aviation Engineering Directorate. Once the AWR is provided, it is sent along with the other documents with a memo, signed by a Senior Level memo requesting an ETP. The AWR is valid for three years.

The sUAS platform used for observation and data collection has real potential for becoming a quick, cost-effective way to monitor the progress of nesting birds in hard to reach places. For this platform to work efficiently and in a manner that collects the best data, some points described below have been found over the past two years to help improve the use of this platform.

Good metadata and a member of the team that has experience with eagle behavior and good knowledge of the territory is key to obtaining useful data. A trained eye for these sUAS platforms was able to compensate for finding nests with sometimes less than ideal video streaming quality or lighting situations. A profile containing pictures from multiple angles and distances and GPS coordinates of known nest in the territory was critical to confirming nest locations and to reduce the time that the sUAS team spent locating nests during a flight.

For the legal operation of the sUAS to fly commercially, Federal Aviation Administration (FAA) regulations require one member of the team to be Part 107 rated as a commercial remote pilot. While the Part 107 remote pilot does not need to be on the controls during flight, he/she must be present and is responsible for lawful compliance of the operation; or in other terms, is serving as Pilot in Command (PIC). To comply with Part 107 while also maintaining the ability to collect high quality data, the sUAS must have some certain technological capabilities. For instance, per Part 107 the sUAS must remain in Visual Line-Of-Sight (VLOS) of the PIC, the person manipulating the controls, and a visual observer without the use of any vision aiding device other than corrective lenses. The sUAS must also remain an adequate distance from a nesting site to not "take" the eagles as per BGEPA requirements. Therefore, to comply with both regulations, a long-range transceiver for video transmission, as well as a high optical zoom HD camera, is necessary to record proper data.

2399 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Both platforms have stabilization systems utilizing software that controls a three-axis gimballed camera mount. An HD camera with a gimbal mount was key to obtaining a clear picture for data collection from long distances and in variable wind conditions. The camera for both sUAS platforms had a 30x zoom which allowed the sUAS to maintain legal distance from nesting sites to avoid disturbing nesting eagles. Long distance video transmission capabilities, in this case greater than one mile, also aided in keeping distance from nesting birds. Both cameras on the platforms had auto focus, though the DJI also provided an intuitive touchscreen focus selector to allow operators to quickly refocus on any part of the camera view angle. In addition, DJI had auto and manual exposure, which was very effective in compensating for harsh shadows and high contrast lighting on cliff faces. Both systems offered the ability to record both photo and video data. However, the DJI provided direct on-board data recording while the E900 only allowed for data to be recorded from the receiver, which led to corruption and degradation of the photos and video due to radio interference. Direct on-board data recording capabilities are vastly preferable as a means of retaining high-quality photos and video. On the other hand, because of the E900's modular components and features, it is able to offer the ability to slave two different controllers to the sUAS which proved beneficial. The ornithologist was able to control the camera gimbal and zoom to find nests with one controller, while the operator was able to fly the sUAS into viewing position using a separate controller.

As mentioned in section 4.2, Dugway has a wide range of temperatures and weather conditions during the observation period. It was found during use of the sUAS that cold temperatures adversely affect battery performance and consequentially the amount of time the drone could spend per flight investigating a territory. This led to increased time in a territory as time would be needed for a battery swap and a second flight to obtain the necessary data. Other weather considerations included windy conditions at the surface as well as at observation altitude. These conditions required more finesse from the pilot, as well as requiring the sUAS to expend more battery power as the gimbal and stabilization systems on the platform worked harder to compensate for the windy conditions and maintain a fixed three-dimensional GPS location. The extra battery power required to hold location ended up limiting the loiter time and range of the sUAS. Comparing the two platforms that were used, it was found that the E900 had better battery power duration and a more compact battery system. The downside of this more compact system was a top-heavy design, which made the E900 more unstable and prone to tipping while landing in a crosswind.

8.2 UAS IMPLEMENTATION

The UAS observation method was the most uncertain upon the start of the 2019 nesting season and it proved to be unreliable as a method of weekly nest observations due to scheduling and payload restrictions. The realities of flight scheduling with RIAC students resulted in flight days that were sporadic. RIAC allowed the use of their students and platforms on an as-available basis, and other missions, weather concerns, or maintenance frequently bumped nest observations off the schedule. In addition, the sections of airspace the students were scheduled for were often not over the desired areas of range containing eagle nests to be surveyed. It became clear to the DPG Team that rather than using the UAS as a stand-alone observation method, it would be more useful as a precision tool for obtaining rapid nest observations in areas with no ground access or with critical range use planned within the next two weeks.

2400 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The UAS platform was unique in that it was able to view nests with no ground access within 2 miles. It also possessed a highly useful thermal camera capability, which could identify a chick within a nest in seconds *(given an appropriate time of day, before the cliff face has heated in the sun).* However, the payloads carried by the UAS fleet in 2019 proved to be inadequate to observe most eagle nests due to low resolution imagery. The HD payload upgrade in 2020 improved the nest-monitoring potential of the platform immensely. The DPG Team does not recommend the use of UAS platforms for nest surveys unless equipped with HD payload capabilities.

If the nest location was well known, the UAS was by far the fastest and most efficient observation method due to lack of drive and hiking time between observation points. However, the nature of the platform's flight and approach patterns made detailed nest metadata critical to the success of the survey. UAS platforms must determine an approach angle and loiter point for a territory observation from several kilometers away, requiring the observation team to have precise knowledge of the nest's location reference data, elevation, aspect, bearing from the ideal viewpoint, and topographical inclusion before the nest can be found. The UAS observation team found that landscape level photos combined with detailed descriptions of a nest's location were sufficient to allow for a successful survey. Without this metadata, the UAS platform was nearly incapable of locating a nest in the time allowed.

The DPG Team found that the most important factor influencing the success of the UAS team was the integration of the biological observer into the military framework of the RIAC students. The civilian observer had to learn the correct protocols and language, as well as establish trust and communication pathways with both the students and the instructors. Once the observer was able to work within the RIAC team, the frequency and success of survey flights increased dramatically. The RIAC students and instructors also found the nest surveys to be useful training experiences. Eagle nests are small, cryptic targets for a UAS operator, which presented the students with invaluable practical experience. The nest metadata was also presented in the style of a mission packet, allowing the students to practice working with external intelligence to locate a target. The DPG Team highly recommends nest monitoring as a dual-purpose use of UAS platforms, for both natural resource monitoring and student pilot training exercises.

14. ABSTRACT

The U.S. Army's Multi-Domain Operations operating concept is meant to solve the problem of anti-access and area-denial (A2/AD) threats posed by peer adversaries. The primary means of defeating these threats is the Multi-Domain Task Force (MDTF), but the MDTF has potential beyond penetrating A2/AD spaces. This is significant amid the ongoing debate about the U.S. Army's role in the Indo-Pacific. This study examines the capabilities of the MDTF and how it can contribute to the Joint Force in the Indo-Pacific by using a reverse version of the Joint Capabilities Integration and Development System process. This process analyzes MDTF's capabilities based on requirements documents, determines the potential gaps those capabilities can fill, examines how the MDTF can fill those gaps at three key locations in the Indo-Pacific.

This study demonstrates that the MDTF has a unique and flexible mix of capabilities that allow it to perform multiple tasks beyond penetrating enemy A2/AD spaces. These include generating its own A2/AD space to serving as a deterrent to enemy escalation and assisting in maintaining operational access for follow-on forces. The MDTF can also isolate enemy forces and delay or disrupt enemy movements and massing of forces, while providing early warning and targeting information. This enables the MDTF to contribute to Joint Force operations in the Indo-Pacific across all phases of competition and conflict if used to its full potential.

ABSTRACT

OFFENSE INVERTED: NON-STANDARD APPLICATIONS OF THE MULTI-DOMAIN TASK FORCE IN THE INDO-PACIFIC, by David E. Degenhardt, 137 pages.

The U.S. Army's Multi-Domain Operations operating concept is meant to solve the problem of anti-access and area-denial (A2/AD) threats posed by peer adversaries. The primary means of defeating these threats is the Multi-Domain Task Force (MDTF), but the MDTF has potential beyond penetrating A2/AD spaces. This is significant amid the ongoing debate about the U.S. Army's role in the Indo-Pacific. This study examines the capabilities of the MDTF and how it can contribute to the Joint Force in the Indo-Pacific by using a reverse version of the Joint Capabilities Integration and Development System process. This process analyzes MDTF's capabilities based on requirements documents, determines the potential gaps those capabilities can fill, examines how the MDTF can fill those gaps at three key locations in the Indo-Pacific.

This study demonstrates that the MDTF has a unique and flexible mix of capabilities that allow it to perform multiple tasks beyond penetrating enemy A2/AD spaces. These include generating its own A2/AD space to serving as a deterrent to enemy escalation and assisting in maintaining operational access for follow-on forces. The MDTF can also isolate enemy forces and delay or disrupt enemy movements and massing of forces, while providing early warning and targeting information. This enables the MDTF to contribute to Joint Force operations in the Indo-Pacific across all phases of competition and conflict if used to its full potential.

ACKNOWLEDGMENTS

I would like to begin by first thanking my wife Nancy, who has supported my military career since I was an R.O.T.C. Green to Gold Cadet. We transitioned from a deployment directly to coming to CGSC, and there is no way to accurately describe the amount of assistance she has provided over the past ten months as I have been buried in books and research. Next, I would like to thank my committee members Dr. Phillip Pattee, LTC David McCaughrin, and Kathy Strand for their advice and assistance in making this a better thesis and helping to guide my research.

I would also like to thank both of my staff groups for the year. I could not have completed my initial prospectus work without the leaders of 19B who put a tremendous amount of work into succeeding as a group and making sure every member of the group was able to succeed at common core. My companions in the Art of War Scholars staff group 20A have also been an invaluable source of advice and support, particularly my peer review group MAJ Drew Horgan and MAJ Mcleod Wood. Finally, I would like to thank Dr. Dean Nowowiejski for his encouragement as well as the tremendous effort involved in organizing the Art of War Scholars program.

CHAPTER 1

INTRODUCTION

Background

Since its inception in late 2016 under the heading of Multi-Domain Battle the Army's most recent operational concept has undergone continuous revision to more clearly articulate the necessary changes required for the Army to remain competitive in great power competition. Doctrinally the concept of Multi-Domain Operations is built around rapidly and continuously integrating all domains of warfare to deter aggression and compete against enemies at a level below armed conflict. If this option fails, goal of Multi-Domain Operations is to use this integration to defeat the enemy and return to a pre-conflict state on more favorable terms for the United States and its allies and partners.[1]

To solve problems with Multi-Domain Operations the Army has identified three central tenets: calibrated force posture to position and maneuver forces on a strategic scale; using "multi-domain formations [that] possess the capacity, capability, and endurance necessary to operate across multiple domains in contested spaces against a near-peer adversary" and convergence or "rapid and continuous integration of capabilities in all domains … that optimizes effects to overmatch the enemy."[2] Despite the flexibility of these tenets, in conflict Multi-Domain Operations is usually described as a solution to

[1] U.S. Army Training and Doctrine Command (TRADOC), TRADOC Pamphlet 525-3-1*: The U.S. Army in Multi-Domain Operations 2028* (Fort Eustis, VA: TRADOC, December 2018), 17.

[2] Ibid., vii.

2422 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

anti-access and area denial (A2/AD) threats posed by peer adversaries where forces will penetrate the enemy's A2/AD systems, dis-integrate enemy forces, and then exploit the resulting openings to achieve joint force objectives.[3] This reflects our focus on and preference for offensive maneuver, with shaping and defensive operations taken as a secondary consideration.

One of the methods that has been used to develop Multi-Domain Operation as a concept has been the Multi-Domain Task Force (MDTF), which was directed in 2017 as part of a deliberate process of design and experimentation. The MDTF was conceptualized as a forward-stationed brigade-sized unit combining long-range precision fires, integrated air and missile defense, and special capabilities such as electronic warfare, space, cyber, and information operations before and during conflict.[4] The first MDTF was established at Joint Base Lewis-McChord in 2017, and the Army currently plans to establish five MDTFs with two in the Indo-Pacific, one in Europe, one in the Arctic, and one as a global response force.[5]

Over the last four years the MDTF at Joint Base Lewis-McChord has participated in numerous training exercises including Yama Sakura 75 in 2017, Pacific Sentry in

2423 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2017, Rim Of The Pacific in 2018, and Valiant Shield in 2020.[6] These exercises have provided valuable insights on integrating the MDTF into the Joint force, particularly in terms of operating across domains while integrating and synchronizing cyber and space effects. Based on the outcome of these exercises the MDTF as a concept has arguably been validated, bringing a much-needed ability for the Army to contribute to conflicts occurring in domains that have historically favored other branches of the United States military. The multinational nature of many of these exercises also demonstrates the role that the MDTF can play in enabling operations alongside our allies and partners.

This is particularly important as TRADOC Pamphlet 525-3-1 takes the unusual approach of specifically naming China and Russia as serious threats and orienting the Multi-Domain concept against them.[7] While both states operate within the Indo-Pacific Theater where the first MDTF is postured, the bulk of Russia's population and forces are concentrated closer to Europe. As a result, China represents the greater threat to U.S. interests in the region and will be treated as the primary adversary within this study.

Despite these benefits the MDTF and Multi-Domain Operations are still in their doctrine development phase, with the latter mostly existing as a conceptual discussion that is slowly percolating through the minds of senior leaders and rising through the ranks carried by field grade officers who have been introduced to the concept through schooling and exercises. The second MDTF was officially activated on 16 September

[6] Brian J. Newill, "Leveling Up: Improving Army Fires and Targeting for Multi-Domain Operations," in *Theater Army in Multi-Domain Operations Integrated Research Project*, ed. Gregory L. Cantwell (Carlisle, PA: Army War College, 2020), 147.

2021 and as of yet only has a fraction of its eventual total of about 1,200 Soldiers.[8] A number of the MDTF's required capabilities are still in development, including Mid-Range Capabilities (MRC) and Long-Range Hypersonic Weapons (LRHW) that will not be fully operational until at least 2023.[9]

According to this emerging doctrine the purpose of the MDTF is to use kinetic and non-kinetic capabilities to neutralize an adversary's A2/AD systems to support the Joint Force.[10] This does not account for a basic principle inherent in their design: the same capabilities that allow a force to *penetrate* an A2/AD space can also be utilized to *generate* an A2/AD space. This provides for a number of potential uses for an MDTF that are not captured in the Multi-Domain Operations concept that this study will explore.

The roots of this principle can be found in the 2017 RAND study titled *What Role Can Land-Based, Multi-Domain Anti-Access/Area Denial Forces Play in Deterring or Defeating Aggression?* This study identifies three possible approaches that include attacking enemy A2/AD, mitigating damage from enemy A2/AD, and creating A2/AD challenges for adversaries.[11] Written at approximately the same time that the MDTF was

being developed, this report does not mention the MDTF but forecasts many of the capabilities that the MDTF now possesses. While this report appears to have largely been forgotten as the MDTF has been designed around the first approach, many of the recommendations and conclusions in the report suggest that the MDTF has significant unrealized potential to assist in the third approach. Clarifying and exploring this potential increases the flexibility of MDTF and provides additional options for conducting Multi-Domain Operations that will increase the Army's relevance, capabilities, and relevance in the Pacific Theater.

Without referencing the MDTF, the RAND study also suggests the development of a small and specialized Army unit with longer-range anti-ship capabilities for pre-crisis or rapid deployment. This is described later in the study as a notional A2/AD system that integrates sensors, anti-ship missiles, and antiaircraft batteries within a combined force.[12] This is remarkably like the eventual make-up of the MDTF, although the MDTF and its doctrinal use developed along a different path focused on penetrating A2/AD spaces rather than creating them.

The study goes further by suggesting several locations where such a unit could be useful in scenarios concerning Taiwan, the South China Sea, or the Senkaku Islands.[13] These suggestions are no more than hypothetical cases, however, and do not consider the

2426 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

capabilities of the MDTF or template possible opposing forces and how the MDTF might fare against them. The purpose of this paper is to build on this earlier research by objectively examining the MDTF's capabilities, determine what tactical tasks it can fulfill outside of its primary use of defeating adversary A2/AD systems, and examine the possible outcomes of using the MDTF in these roles.

Despite the reality that the full operational capabilities of the MDTF as templated will not be available until at least 2023, there is sufficient information available based on the unit's design documents and equipment that is being tested to allow for analysis of the potential uses for a MDTF to fulfill these roles outside of its doctrinal mission. These uses could take advantage of dis-integrating elements of the MDTF to allow portions of the task force to operate independently in several key locations or extending and overlapping coverage from different assets to create a distributed A2/AD bubble.

Maintaining China as the pacing threat in the Indo-Pacific Theater suggests several potential locations where a MDTF could provide a key defensive or deterrent capability. China's increasing naval presence west of the Malacca Strait creates the possibility that denying access to the straits during conflict could effectively split the Chinese Navy and prevent it from massing naval combat power for hours or days. Another example would be deployment of a MDTF to the Philippines, Malaysia, or Vietnam to affect territorial disputes within the Nine Dash Line and potentially intervene in a crisis. In the event of a Chinese attack on Taiwan, its long-range capabilities could also allow a MDTF to influence operations in the Straits of Taiwan from a variety of locations and shield approaching U.S. forces if the United States decided to oppose a forceful reintegration of Taiwan and China. Finally, as referenced in the RAND study the

2427 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MDTF might be able to play a role in support of Japan in the event of a dispute over the Senkaku islands.

Problem Statement

The Army's MDTF is a brigade size element with a mix of unique capabilities which has been primarily designed around a specific offensive role, severely limiting its flexibility and ability to act within a large theater. Failing to account for other tasks that the MDTF might be capable of performing has stifled development of doctrine that could potentially employ it in any other capacity beyond penetrating A2/AD spaces. Overfocus on a single mission has resulted in a general lack of understanding of the precise capabilities that the MDTF was designed to employ, making it difficult for planners to imagine ways that it could potentially be used in shaping or defensive operations that could affect the operational and strategic balance of a theater of war. This is particularly important in the Indo-Pacific, where the United States Army is re-evaluating the role of land component forces and their relevance due to the vast distances between landmasses and limited ground maneuver space.

Purpose of the Study

This intention of this study is to provide a more comprehensive understanding of the doctrinally designed capabilities of the MDTF and how those capabilities can be used in future conflicts beyond the MDTF's planned role of penetrating an A2/AD space. While this study will focus on the Indo-Pacific theater, grounding the study in research on operational capabilities and doctrinal tasks will enable scholars and planners to transfer the resulting conceptual uses of the MDTF into different locations with minor

2428 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

modifications based on different operating environments and mission variables. By illustrating the capabilities of the MDTF and potential methods of using those capabilities this paper is intended to generate further discussion on the issues addressed as well as providing a starting point for the development of doctrine that will allow the MDTF to take a greater role in conducting large-scale combat operation and suggest potential roles for Army capabilities in the Indo-Pacific.

Research Questions

The primary research question for this study is how the MDTF can contribute to the Joint Force in the Indo-Pacific outside of its doctrinal mission of penetrating A2/AD spaces. This research question was chosen due to ongoing debate about the role of the Army in the Indo-Pacific theater and because the first and most operationally mature MDTF in the Army's inventory is currently aligned against that region. Providing an answer to this question will provide additional options for joint planners to incorporate a unique mix of capabilities into future conflicts that allows for increased flexibility and methods of shaping the operational and strategic picture using long-range precision fires.

To answer this primary research question, the first secondary research question asks what the planned future capabilities of the MDTF are based on its designed structure. As the analysis in chapter four will demonstrate, the existing MDTF does not match the unit's force structure requirements documents while informational presentations crafted for mass consumption have largely been simplified to top level line and block charts. A large part of this discontinuity has come from the MDTF being designed around capabilities that are only now reaching the point of being tested and

2429 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

issued. Envisioning future uses for the MDTF requires a solid understanding of the potential capabilities that the unit is intended to possess.

This ties directly into the second secondary research question, which asks what operational and tactical tasks the MDTF can perform outside of its existing doctrinal mission based on those potential capabilities. The answer to this question requires thorough analysis of the capabilities stipulated in the MDTF's original design documents plus additional capabilities still in development. These should then be measured against doctrinal tasks to ascertain if the MDTF is capable of accomplishing those tasks. Laying a solid foundation of essential basic warfighting tasks and potential tasks that the MDTF can perform sets the stage for applying those tasks against key locations in the Indo-Pacific region and demonstrating the potential impact that a fully realized MDTF could have as a force multiplier if employed as part of a joint strategy supporting national objectives.

The third secondary question addresses this area by asking how the MDTF's capabilities and the associated tasks it can perform can be used to shape the operational and strategic environment in the Indo-Pacific. A definitive answer to this question would constitute a theater campaign plan or a major operational plan, so this study examines a handful of key locations in the Indo-Pacific and use the answers to the first two questions to demonstrate potential uses for the MDTF at those locations. This will allow the question to be answered in terms of strategic and operational military effects that an MDTF can potentially generate, allowing for those effects to be generalized for use in future operations at different locations. This brings us back to the primary research

2430 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

question by providing a menu of options showing how an MDTF can allow the Army to contribute to the Joint Force in the Indo-Pacific.

Assumptions

The main assumptions used in this study are based around equipment capabilities, requirements, organizational/doctrinal design documents, and use of the MDTF in hypothetical locations. For the first category, this study will assume that announced ranges and velocities are reasonably accurate for planning purposes. This allows for use of publicly available sources and provides a basis for comparison between various capabilities as well as the possibility of deriving employment concepts based on those capabilities. This includes using the SM-6 and Tomahawk ranges and flight speeds when conjecturing about the possible uses and role of the MDTF's planned mid-range capability. Another example of such an assumption would be quoted speeds and ranges of long-range hypersonic weapons currently in development.

In terms of requirement and design documents, this study assumes that the capabilities described in requirement documents provide an accurate representation of the MDTF's intended design. The most recent active design documents will be considered as authoritative statements of the planned organizational, personnel, and equipment structures of the MDTF, and the listed capabilities will be used to analyze the planned MDTF's suitability for doctrinal tasks. This includes the intended roles for sub-elements of the MDTF and specific capabilities housed within its component battalions. This is particularly necessary when analyzing the I2EWCS battalion since many of the templated capabilities are specifically designed to support a particular aspect of the MDTF's role

2431 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

while the exact nature of how those functions would be performed are not publicly available.

The final set of assumptions in this study is concerned with exploring potential uses of the MDTF within the Indo-Pacific. Due to the complex politics of the region and the continuing evolution of relationships among the United States and its allies and partners this study will assume that deployment to strategic locations will be allowed by all participants for the purpose of illustrating the MDTF's capabilities. This enables the study to proceed without an in-depth analysis of the political situation around each potential deployment of the MDTF. As a result, the proposed uses of the MDTF can be applied in the future if conditions change or generalized to apply to locations similar to the ones chosen for this study.

Definition of Terms

Domain – "an area of activity within the operational environment (land, air, maritime, space, and cyberspace) in which operations are organized and conducted."[14] The first four are physical, while cyberspace is "a global domain within the information environment."[15] There is considerable overlap between domains.

Multi-Domain Operations – "Operations conducted across multiple domains and contested spaces to overcome an adversary (or enemy's) strengths by presenting them with several operational and/or tactical dilemmas through the combined application of

[14] TRADOC, TRADOC Pamphlet 525-3-1, GL-4.

[15] Office of the Chairman of the Joint Chiefs of Staff (CJCS), *DOD Dictionary of Military and Associated Terms* (Washington, DC: The Joint Chiefs of Staff, November 2021), 55.

2432 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

calibrated posture; employment of multi-domain formations; and convergence of capabilities across domains, environments, and functions in time and spaces to achieve operational and tactical objectives."[16]

Multi-Domain Task Force – "theater-level maneuver elements … [that] synchronizes precision effects and precision fires in all domains against adversary A2AD networks in all domains, enabling joint forces to execute their OPLAN-directed roles." [17]. They are "designed to deliver long-range precision joint strike as well as integrate air and missile defense, electronic warfare, space, cyber, and information operations."[18]

Anti-Access Area Denial (A2/AD) – a combination of "capabilities, usually long-range, designed to prevent an advancing enemy force from entering an operational area" (anti-access) and "capabilities, usually short-range, designed to limit an enemy force's freedom of action within an operational area" (area denial).[19]

Long Range Precision Fires – capabilities designed to "attack, neutralize, suppress, and destroy targets using missile-delivered indirect precision fires."[20] There is no defined maximum range, but the Acquisition Support Center specifies that these fires

2433 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

will replace the Army Tactical Missile system and have a range in excess of 300 kilometers.[21]

Mid-Range Capabilities – an intermediate capability "designed to hit targets in the range between the Precision Strike Missile and the Long Range Hypersonic Weapons." [22] The current version of this capability is expected to be built around the SM-6 and Tomahawk missile.[23]

Long Range Hypersonic Weapon – a developing capability intended to allow the United States military to launch missiles from a ground platform at a speed of over 3,800 miles per hour with greater ranges than mid-range capabilities.[24]

Scope

This study will focus on the potential uses of the MDTF within the Indo-Pacific theater based on the MDTF's intended capabilities once all included components have been fielded. It will include the MDTF's long range fires capability, I2EWCS battalion, and integrated air and missile defense elements. These capabilities will be analyzed against existing tasks described in Army doctrine and how those tasks can be implemented in select locations within the theater. The selected locations are intended for

illustrative purposes and do not represent an exhaustive list of all possible locations that the MDTF could be deployed. Finally, the potential uses of the MDTF from this study are intended to be generalizable to similar locations and situations and are not specific to the examples provided.

Limitations and Delimitations

The primary limitation of this study is that it can only use unclassified or open-source weapon system ranges and capability information to prevent classification and foreign disclosure issues. EW, Cyber, and Space capabilities are often highly classified and operational details concerning the precise effects that these systems can generate are not available in open sources. Many of the capabilities listed are at varying stages of development and their final operating parameters have not yet been precisely determined. To proceed, this study will use the most current test results and announced capabilities for research and planning purposes. If this study requires calculations to determine hypothetical factors such as line of sight or detection range of an intelligence gathering capability these calculations will be based on open-source information to preserve classification.

Delimitations applied to this study include the choice to limit the study to assessing potential uses of the MDTF in the Indo-Pacific and the decision to include only fielded weapon systems or weapon systems with prototypes currently being tested This study also only uses the Army's current list of tactical tasks without exploring possible new tasks that could be derived from the capabilities of the MDTF in order to limit the amount of analysis to a manageable level. For a similar reason, the number of example scenarios used to illustrate the potential impact of employing the MDTF will be restricted

2435 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to theoretical potential scenarios based on the results of the literature review in Chapter Two. The primary focus of this study will be on the use of the MDTF in the islands and archipelagos within the Indo-Pacific rather than potential operations on the mainland, as the Army already has sufficient understanding of its role in such a campaign.

Significance of the Study

The significance of this study is that it expands the doctrinal concept of the MDTF outside of its current role as an A2/AD breaching instrument and provides a starting point to consider alternate offensive and defensive uses of the MDTF as part of Multi Domain Operations within the Army Concept Framework. Expanding the MDTF's doctrinal role or describing a multi-purpose role allows for increased flexibility in using these units to generate effects on an operational and strategic level to shape the theater by restricting or denying key movement corridors and strategic locations to enemies. This assists the MDTF in providing freedom of movement for joint forces conducting follow-on operations and demonstrates an additional role for the United States Army in future operations in the Indo-Pacific.

Summary

The concept of Multi-Domain Operations has flown quietly under the radar for much of the Army outside of the Pacific theater, even as the Army prepares to release new versions of ADP 3-0 and FM 3-0 to bring the concept fully into common use. Because of this there has been relatively little intellectual engagement with the doctrinal vision there is considerable work ahead if the United States Army intends to reach the 2028 milestone in the Army Concept Framework. The current operational concept has

2436 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

been narrowly focused on offensive operations and does not adequately address the role of international partners in strategic roles. In order to be viable as doctrine, Multi-Domain Operations must be fleshed out and explored through imaginative applications and scenarios.

One of the best methods to accomplish this goal is through engagement of hypothetical case studies, which can serve as a starting point to expand doctrine or serve as the foundation for future exercises and war games. The problem in this case is that the prime experimental laboratory for Multi-Domain Operations, the Multi-Domain Task Force, has been designed around a specific offensive role although some of its components have the potential to be used in other offensive roles or in a defensive situation. This prevents the MDTF from living up to the full potential of its intended capabilities and limits its utility in future conflicts. This problem is particularly exacerbated in the unique operating environment of the Indo-Pacific, which has often been viewed as being dominated by naval forces.

This study is meant to take a fresh look at the MDTF in terms of its intended capabilities and examine the potential gaps that they could be used to fill rather than remaining focused on the specific mission for which it was designed. Comparing these capabilities against the menu of Army tasks allows us to envision additional ways that the MDTF could be useful in the operating environment where it was first developed. Examining these methods of employment through the lens of strategically important locations builds on this concept and provides examples of potential ways that the MDTF could provide a strategically significant capability in support of a joint force before large scale combat operations begin and during the initial phases of conflict. This provides

2437 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

additional flexibility to joint planners as well as an additional tool to be used during operational design to affect the movement and deployment of adversary forces.

Before conducting this analysis, it is important to ground the research and further examine the questions that this study is intended to answer by conducting an open source literature review examining previous work that has been completed related to the subject of operational and response forces with multiple organic capabilities. While the concept of Multi-Domain Operations is still in development and the MDTF is a relatively new unit, there has been some initial work written to explain the general concept of Multi-Domain Operations to the force at large and a body of joint doctrine that can be applied to provide insight into how MDO can interface with those force structures and formations.

The Indo-Pacific region and its general security situation has also been the subject of numerous studies as China has continued to develop new capabilities and worked to expand its influence with neighboring countries. Reduced operations in the Middle East have led the Army and joint planners to raise the question of what the Army can contribute to operations in the Indo-Pacific theater, while others have begun engaging in studies on specific applications of MDO as a concept and some limited inquiry into its application within specific sub-fields of Army operations.

CHAPTER 2

LITERATURE REVIEW

Introduction

As a relatively new operational and strategic concept that has not been fully implemented, literature concerning Multi-Domain Operations and the Multi Domain Task Force is relatively limited. This literature and has undergone a great deal of change over the last few years as these concepts have been developed. This presents a significant challenge when conducting a literature review, especially when examining a novel application of the concept. A great deal of the work that has been completed on this subject resides in prior theses, and monographs written by military officers, professional military education faculty, CGSC students, and students at the School for Advanced Military Studies (SAMS). The remainder can be found in think-tank studies, recent news stories, and journal articles written by national security thinkers on Multi-Domain Operations and the strategic situation in the Indo-Pacific. An additional barrier is that much of the literature on Multi-Domain Operations exists as the classified level and is not available for this study.

The primary research question for this study asks how the MDTF can contribute to the Joint Force in the Indo-Pacific outside of its doctrinal mission of penetrating A2/AD spaces. Because this question is focused on the intended capabilities of the MDTF and what those can contribute, the first secondary research questions is designed to analyze the capabilities of the MDTF based on its design documents and emergent technologies. The second secondary research question compares those capabilities to tactical mission tasks and then applies the valid tasks against joint doctrinal concepts

2439 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

based on the range of military operations. The third secondary research question takes the data from the first two secondary research questions and places it in the context of the Indo-Pacific to provide data to determine the potential impacts that the MDTF can generate.

Conducting a literature review concerning these questions is complicated due to the limited body of work that specifically addresses the MDTF in any role outside its designed use of penetrating A2/AD spaces. The idea of a defensive strategic role for the MDTF has been alluded to in some publications and policy documents but has not received the same level of analysis as the MDTF's original and primarily offense-oriented mission. At the same time Army's role in the Indo-Pacific has been a topic of contention over the last few years while there has been an emerging body of work dedicated to China's growing influence in the region as well as the strategies China is likely to use in future conflicts. As a result, the literature review process related to the questions of this study will be largely focused on recent documents in order to provide the most current understanding of the operational environment used in this study.

The process for identifying sources for this literature review began with an examination of doctrinal literature beginning with TRADOC Pamphlet 525-3-1 and expanded to additional relevant Army and Joint documents to provide an overview of the topic. The next step was examining the last four years of CGSC MMAS Theses and SAMS Monographs for topics related to Multi-Domain Battle, Multi-Domain Operations, and the Multi-Domain Task Force. Each document found was assessed for relevance to the topic and analyzed, identifying additional sources that had been referenced in their bibliographies. In addition to this procedure the Defense Technical Information Center

2440 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

provided access to some background material and potential sources for analysis. Finally, well known strategy-oriented print journals, online journals, and curated websites provided recent articles related to this study's research questions.

Based on the outcome of this initial research this literature review will primarily examine four major areas of existing research related to the primary and secondary research questions. The first of these areas will be an examination of existing doctrine relating to Multi-Domain Operations, related Joint Doctrine, and other official military documents related to the MDO concept. The second area will examine existing literature on Multi-Domain Operations and the MDTF as well as related tactical concepts. The next area will provide a brief background on recent studies of the Army's role in the Indo-Pacific and current discussion on what that role might entail. Finally, the fourth section will discuss pertinent literature on the security situation in the Indo-Pacific, key strategic locations in the region, and the security posture of countries surrounding these points. There is considerable overlap between these categories, with each reviewed document being placed according to its primary focus.

Doctrinal and Military References

Pending the release of the next version of ADP 3-0 in 2022 the current capstone document for Multi-Domain Operations is TRADOC Pamphlet 525-3-1, *The U.S. Army in Multi-Domain Operations.* The primary purpose of this reference is to introduce the MDO framework to a new audience, define the operational environment, express basic tenets, and present problems facing the new construct for future consideration and development. As a result, it introduces MDO at a broad conceptual level expressed in terms of three tenets: calibrated force posture, multi-domain forces, and convergence.

2441 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The existing MDO framework it describes is overwhelmingly focused on offensive operations, moving from competition directly into penetration, dis-integration, and exploitation. The limited discussion of defense presented focuses on denying an enemy specific objectives and force protection considerations rather than shaping the larger strategic context.[25]

Chief of Staff Paper #1, "Army Multi-Domain Transformation" provides further expansion on the topic of MDO and extends the previous concepts into a more complete operational picture. Relevant to this study the paper discusses contesting adversary movements to provide time to consolidate gains and de-escalate, use of the Army to secure key locations such as the Malacca Strait, and using land-based capabilities to affect other domains.[26] This provides a foundation for use of MDO in strategically significant defensive operations, but does not specify exactly what capabilities would be used in these instances or how they would integrate with multinational forces.

TRADOC Pamphlet 525-3-8 sheds some light on these areas by marrying aspects of Large-Scale Ground Combat Operations with MDO, addressing the need to shape the environment through employing forces and capabilities but only describes key terrain in terms of collapsing enemy air defense and fires capabilities. Employment of partner capabilities is discussed in terms of converging effects and conducting security cooperation activities to set the theater, as well as forming large multinational combined

2442 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

arms formations.[27] This formulation includes operations conducted in concert with partners but does not envision or detail close cooperation at brigade level or below. While reflective of how the United States has generally conducted operations in the past, this may not be an ideal model for future high-intensity high-tempo operations.

Congressional Research Service Documents such as *The Army's Modernization Strategy: Congressional Oversight Considerations* and *Defense Primer: Army Multi-Domain Operations* also provide some insight into development of the MDO concept. The first of these addresses MDO challenges and links them to the Army's six major modernization priorities, as well as raising the question of whether modernization will address the military strategies of peer competitors.[28] The *Defense Primer* provides a basic overview of MDO with updated information discussing the Army's Project Convergence Initiative and describes developing MDO concepts with allies and partner nations as well as the potential need to develop a joint warfighting concept for MDO.[29]

Some elements of this joint warfighting concept can be found in other service doctrines, with the most prominent example being Air Force Doctrine Publication

(ADFP) 3-99. Described as emerging doctrine, AFDP 3-99 addresses the Air Force's role in Joint All-Domain Operations (JADO) and includes discussion of competition in that framework as well as the necessity for Joint All-Domain Command and Control (JADC2).[30] In addition, AFDP 3-99 is organized by warfighting function and provides an avenue to consider for future expansion of how the Army describes and explains MDO as the concept becomes operational in the larger force.

This kind of nesting is also applicable when examining the methods of employing U.S. forces alongside partner forces, which is a key consideration within the Indo-Pacific region. While this study focuses on the MDTF operating semi-independently, multinational support and transportation may be required to reach key locations. Joint Publication 3-16, *Multinational Operations* provides guidelines to consider for multinational operations, including organizing and operating parallel command structures as well as coordinating between forces .[31] The Army's Field Manual (FM) 3-16, *The Army in Multinational Operations* provides more detail on these concepts as the operational and tactical level, addressing specifics concerning North Atlantic Treaty Organization and Combined Forces Command Korea operations along with discussions

of interoperability and incorporating national capabilities.[32] While not specifically MDO centered, these publications provide some idea of the challenges in supporting and conducting operations in a complex operating environment.

Multi-Domain Operations and MDTF Studies

The concept of Multi-Domain Operations has undergone significant evolution since its inception in 2016. Originally conceived as Multi-Domain Battle, one of the first examples of the concept was Mike Redman and Major Joseph Easterling's Army white paper describing a new concept of combined arms that would utilize cross-domain synergy to fight against peer threats.[33] By the following year General David Perkins was writing about the topic in *Military Review*, focusing on operations in a contested environment and the need to integrate electronic warfare and space capabilities into the battlefield of the future.[34]

As an emerging concept Multi-Domain Battle invited discussion, with junior officers wrestling with the concept as they attempted to reconcile new ideas with existing doctrine. Jonathan Bott and an assemblage of other field grade officers from across all

2445 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

four branches of the Department of Defense examined Multi-Domain Battle in 2017 and identified requirements for a mental shift, education and training, and incorporation of mission orders to drive execution of organizational change.[35] Based on this and other joint collaborations, there were early indications that the MDO concept could evolve into a joint concept as discussed earlier in the doctrinal references. Another example occurred with Shawn Woodford's short article describing Army and Marine Corps collaboration to develop Multi-Domain Battle as a combined arms framework that could be used for tactical application.[36] By 2018 the concept was being used in case studies at SAMS, as demonstrated by Jose Liy's examination of how Multi-Domain Battle had emerged from earlier doctrines.[37]

Multi-Domain Battle officially evolved into Multi-Domain Operations by September 2018, as explained in General Stephen Townsend's article addressing the change in concept. The main factor in this change was the addition of competition and actions below the level of armed conflict, elevating the concept above the tactical level.[38]

Jonathan Bott, now in his capacity as a SAMS student, began exploring this concept as early as 2017 in his monograph arguing for Multi-Domain Operations as an evolution beyond Joint Operations. This represented an early development of the concept, especially factors related to simultaneous operations in multiple domains by one or more departments and how one domain could open vulnerabilities into another.[39]

One of the key developments in the development of MDO theory has been the application of overarching operational design considerations through an MDO framework. Scott Vanoort's 2020 thesis provides one example of this expansion by addressing operational risk in Multi-Domain Operations and updating the risk construct for the modern operating environment. Vanoort concludes that MDO needs to be integrated into joint doctrine while addressing the short timelines of high-tempo operations and pushing authorization authority to lower echelons.[40] These considerations are particularly relevant when addressing an organization like the MDTF that may operate while geographically separated from higher commands in a contested environment.

Current authors have begun to explore applications of MDO in relation to specific military functions and operations. Anthony Clas's article on the challenges of command in multi-domain formation addresses these in terms of emerging technologies, new

[39] Jonathan W. Bott, "What's After Joint? Multi-Domain Operations as the Next Evolution in Warfare," (Monograph, School of Advanced Military Studies, U.S. Army Command and General Staff College, 15 March 2017), 1, 5.

ethical dilemmas in operations, an operational environment that includes dense urban environments, and changes in the roles of leaders and soldiers due to increased complexity in operations.[41] Darren Buss expands on this concept in his participation in an Army War College project, examining the capability of echelons above brigade to command multi-domain operations and control partner units.[42] This addressed the command and control joint warfighting function, a key organizing concept for implementing MDO.

Another example of this concept is the Army's functional concept for fires from 2020-2040. While not specifically addressing MDO, this manual describes many of the fundamental aspects of that concept. This includes leveraging multi-national capabilities, convergence, and cross-domain fires.[43] A third example is Chris Sadoski's thesis, which references Multi-Domain Battle but occurs on the cusp of the transformation between that concept and Multi-Domain Operations. Sadoski examined the requirement for supporting large scale deployment against a peer threat in the context of corps size elements in a rapid response force.[44] These studies and manuals help to align the rest of the force in

support of MDO, providing some context for how other parts of the Army relate to the forces that are most heavily involved in conducting operations.

Regarding this study a more relevant consideration is how MDO specifically should be used to counter peer threats. One example of this is Nicholas Stafford's analysis of whether Multi-Domain Operations can be used to counter Russian hybrid warfare in the Baltics. Stafford examined this scenario in terms of a "*fait accompli"* with Russia having already set up A2/AD systems in the Baltics. Stafford assessed that current capabilities cannot enable quick penetration of an A2/AD space and that requirements for synchronizing effects would present difficulties in exercising mission command.[45] Stafford's framework is worthwhile because it contemplates MDO in a conflict against a specific enemy, but less useful in context of this study because it is focused on using conventional forces in an MDO role and does not address the MDTF as a concept.

The complement to addressing how MDO should be used to counter peer threats is how peer threats will seek to counter MDO. Larry Wortzel makes the argument that China is aware of the U.S. MDO concept and is intentionally designing its strategies around defeating it. Wortzel sees China's focus on A2/AD through this lens and then extends the concepts further by addressing China's novel capabilities with possibilities like the use of electromagnetic pulse weapons to disable electronic capabilities or use of ballistic missiles to threaten adversaries.[46] This underscores the importance of developing

a fully fleshed-out MDO concept that uses the MDTF and other units in multiple capacities so that they are not so easily predictable.

The U.S. Army's Role in the Indo-Pacific

In recent years one of the cornerstone issues of the debate over Pacific strategy has revolved around the question of what forces will lead in the area, with naval and air forces generally considered as being dominant while the Army struggles to make a case for its own inclusion. The vast distances between land masses and islands in the region have long been cited as proof that the Army would have little role in conflicts in the area, but this perspective is ahistorical and does not account for the full range of the Army's developing capabilities and demonstrated ability to influence other domains. Even the island-hopping campaigns of World War II saw significant Army participation, and there are few reasons to think that future conflicts would not also be heavily reliant on Army capabilities.

The RAND Corporation's 2014 study, *The U.S. Army in Asia, 2030-2040*, argues for six main roles for the U.S. Army in Asia including defending key facilities from air and missile attacks, projecting combat forces into theater, and contributing to new deterrent options. Although it predates the creation of the Multi-Domain Task Force, the study includes references to many of its elements and suggestions for how they could be useful in Asia. This includes a definition of expeditionary combat power that includes long-range precision fires, defensive cyber operations, and strategies to turn China's

A2/AD strategy against them using shore-based capabilities and threats to blockade and restrict the Chinese military from establishing conditions necessary to initiate hostilities.[47]

These ideas are further developed in the body of the text, based on the concept that time is a major consideration in any potential conflict against China and that any ability to slow down or delay Chinese operations to allow additional forces to intervene works in favor of the U.S. In order to facilitate this, the authors suggest the possibility that the Army should operate in a coastal defense role or gain control of straits to control access through those waters using mobile, shore-based anti-ship missiles. This would serve as a deterrent by undermining Chinese confidence in a successful naval conflict, but the study does note that there is significant risk that this strategy could increase the risk of conflict or drive China toward a more expeditionary posture.[48] While the current MDTF does not incorporate the deterrent or A2/AD concepts this study calls for in its designated mission, the similarity in unit structure to what the study suggests indicates that it could be used in these roles.

Several years later Emily Martin and Samantha Wooley referenced this study and developed the ideas further in "The Army's Role in the Future Pacific Theater." Based on an earlier symposium on land forces in the Pacific Martin and Wooley argue that Army forces should be able to sink a ship, shoot down a missile, and shoot down the aircraft

that fired the missile within a short window. This article specifically mentions Palawan in the Philippines as a possible site for such actions and discusses the possibility of mobile land-based forces being used to create an A2/AD shield.[49] Without specifically mentioning the MDTF, this article presents another example of a multiple roles that the Army can play in the Pacific that could be within the potential capabilities of the MDTF.

Loren Thompson advanced similar issues the following year in an article in *Forbes Magazine* titled "How the U.S. Army Can Play a Much Bigger Pacific Role Deterring China." Thompson proposes a role for U.S. Army in defeating Chinese naval and air forces trying to traverse the first island chain, suggesting that the Army could establish a major land presence in the archipelago or be based in countries like Vietnam. Thompson references multi-domain operations without bringing up the MDTF, but does discuss long range precision fires, possibly adapting Navy anti-ship missiles for Army use, and the Army's role in providing air and missile defense.[50] Bringing together these functions under a single heading seems to point directly toward the MDTF as a potential method to fulfill these requirements, but Thompson does not make the connection.

More recent discussion in the last year has explicitly tied the MDTF to providing long range precision fires in the Pacific, including Jen Judson's article in October of 2021 on the U.S. Army's desire to carve out a role in the Pacific. Judson initially focuses her

2452 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

attention on establishing relationships and training partners, but also notes that the Army's current priority is developing long-range fires due to the problem of distance in the Pacific and names the MDTF as the primary purveyor of that capability. Judson also brings up criticism of the idea, citing calls for the Army to focus on air and missile defense in the region and arguments that the U.S. Air Force and its bomber force are a better investment than ground-based missile capabilities.[51] The reference to the MDTF here is notable in that it references long-range precision fires but does not specify an anti-A2/AD role, suggesting other uses for the MDTF's capabilities.

The most up-to-date conception of the role of the Army in the Pacific has been based on comments by the Secretary of the Army, Christine Wormuth, on how she sees the Army's mission in the theater. Andrew Eversden from *Breaking Defense* quotes Wormuth as laying out five primary roles including building and defending bases, providing C2, sustaining logistical supply lines, taking an offensive role with long range precision strike capabilities, and counterattacking in the event of enemy incursions.[52] John Grady of the United States Naval Institute digs deeper into the meaning of these comments and notes that many Indo-Pacific nations have cyber, space, and long-range fires in their armies while describing the Army's service role in terms of providing air and missile defense, network security, and the use of long range fires and hypersonic

2453 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

missiles. Crucially, Grady frames these roles in terms of Multi-Domain Operations taking its place as the current doctrine for operations.[53]

The most detailed explanation of these roles and how they would be accomplished comes from Caitlin M. Kenney's article from *Defense One*, which provides an expanded purpose and possible means for each task. Crucial to the discussions in this study is Kenney's explanation of the fourth task of providing ground-based fires, which Kenney indicates includes the ability to interdict fires across sea lines of communications, suppress enemy air defenses, and provide counter-fires against mobile targets. Kenney also references cyber-attacks as a major area of concern and references a need to expand the Army's focus out of northeast Asia and into the southeastern region.[54] These concepts of the Army's use in the Pacific once again leave out the MDTF as a primary executing agent but include many of its components in the Army's projected role and provide some possible tasks that it could execute in a Pacific conflict.

The Indo-Pacific Security Situation

The complexity of the Indo-Pacific security situation is clearly communicated in national security documents, beginning with the *2021 Interim National Security Strategic Guidance* which recognizes that a connection to the Indo-Pacific is vital to our national interests and calls for deepening partnerships with members of the Association of

[54] Caitlin M. Kenney, "Army Would Have 5 'Core Tasks' in a Pacific Conflict," *Defense One,* 1 December 2021, https://www.defenseone.com/policy/2021/12/army-would-have-5-core-tasks-pacific-conflict/187212/.

2454 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Southeast Asian Nations. The guidance also calls for a more robust presence in the Indo-Pacific and places China's assertiveness front and center as a challenge that must be overcome through strong alliances and partnerships.[55] These priorities underwrite the selection of China as the competitor in this study's scenario and show the importance of expanding concepts of defensive partnership.

Although slightly older, the Department of Defense *Indo-Pacific Strategy Report* shares some language with the MDO concept by calling for forward-posturing of combat-credible forces and references interoperable warfighting capability in the region as a force multiplier. This issue is important enough to form the second of the three Lines of Effort in the report, specifically mentioning Singapore, Malaysia, and Indonesia. The report also highlights the importance of the Malacca Strait and addresses the importance of developing the Multi-Domain Task Force and building partner capacity.[56] This suggests some key partners and strategically significant locations, as well and the importance of focusing on their developing capabilities.

Recent testimony and talks by senior Department of Defense leaders have reinforced these ideas, with Secretary of the Army Ryan McCarthy's describing the importance of the Multi-Domain Task Force the possible use of the MDTF as an area denial force in a 2020 statement to the Brookings Institute on the Army's Indo-Pacific

strategy.[57] More recently, Admiral Philip S. Davidson's testimony before the Senate Armed Services Committee included several MDO related priorities such as Long Range Precision Fires and the importance of establishing a multi-domain command and control node in the region.[58] Taken together these statements help to establish the importance of MDO and the MDTF in the region.

The recent release of the Biden administration's new Indo-Pacific strategy has not significantly altered these conclusions. It retains China as a major threat to the rules-based order in the region and lays out five objectives, specifically prioritizing supporting open societies and preventing coercion along with bolstering Indo-Pacific security and building defense capacity of partners such as Taiwan.[59] The strategy also lays out ten lines of effort, with the third line of "Reinforce Deterrence" including references to the Taiwan Strait and AUKUS partnership.[60] Based on these objectives and lines of effort there is still a continued role in the Indo-Pacific for the MDO and the MDTF.

As a result of this emphasis, recent scholarship has focused on the U.S. strategic situation in the region, specifically in relation to China. Although primarily concerned with the Freely Associated States in the Western Pacific, Christopher Lochridge argues

that the United States has a blind spot in the region and addresses China's A2/AD and EW, cyber, and space capabilities as a major concern in the region.[61] George Sotelo describes similar influence tactics by China in the East and South China Sea disputes, arguing that many nations in the region dispute Chinese claims and might welcome U.S. leadership. Sotelo also concludes that China is unlikely to understand or change its behavior for anything short of a military confrontation or a blockade in some situations.[62]

Other authors have examined the possibility of the United States being drawn into a conflict in the region or discussed specific threats China poses to U.S. capabilities. Jacob Rosales imagined two possible categories of scenarios that might lead to U.S. military involvement, with the first being the U.S. acting as a third party on behalf of one or more Southeast Asian nations being threatened by China while the second would be a direct conflict over freedom of navigation operations.[63] Richard Gibson's earlier examination of the region brings the beginnings of MDO into the discussion by addressing China's threat to U.S. space capabilities and potential use of A2/AD systems

and electronic warfare.[64] These studies provide some important insights into some of the possible crises that the U.S. could face in the region as well as some of the barriers to activity based on Chinese capabilities.

One of the foremost authorities on anti-access warfare is Samuel Tangredi, whose 2013 book on the subject laid out what he considers the fundamentals of anti-access warfare including the primacy of geography and the predominance of the maritime domain. Tangredi primarily argues from a maritime perspective, but also makes a larger point that technology and tactics alone cannot defeat a well-developed anti-access strategy.[65] Tangredi further details his arguments in his article "Antiaccess Warfare as Strategy" where he differentiates anti-access warfare scenarios from larger anti-access strategies. In this instance Tangredi's chooses to use the South China Sea as an illustrative example, arguing that a conflict between the United States and China in the region would likely involve multiple elements of national power and a whole-of-government approach.[66] Tangredi's analysis provides a good understanding of anti-access warfare, but does not address the Army's role in defeating or enacting similar strategies.

Major Joseph Cangealose's 2020 monograph on A2/AD threats and their impact on future combat operations provides another perspective on the topic, primarily focusing

2458 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

on the impact of integrated air defense systems as a threat to aircraft. Cangealose ties earlier concepts of A2/AD warfare into Multi-Domain Operations, arguing that surface to air missiles are an effective method of inhibiting opponents from conducting effective Multi-Domain Operations. By using a variety of examples from Vietnam, Israel, and Kosovo Cangealose is able to demonstrate how A2/AD strategies can be used to force aircraft into flight corridors, keep them from maneuvering freely, interrupt an offensive operation by diverting efforts to deal with A2/AD forces, and lessen the effectiveness of strike aircraft.[67]

Narrowing the scope to potentially significant locations where the MDTF may be able to create an outsized effect on events within the theater the Malacca Strait has been the focus of a significant amount of analysis as a key strategic location. Peter Rimmer and Paul Lee's exploration of potential consequences identified sea lane closure in the region as catastrophic to the world's economy and identified numerous key locations where the Straits are narrow enough that this could present a significant threat. Their analysis also included the distance and time costs of going around Indonesia to the Lombok Strait as more than 2,500 nautical miles and upwards of 100 hours depending on the speed of the ship at sea.[68] This underscores the strategic importance of the region that

led to it being chosen for this study, as well as demonstrating the possible strategic benefits of denying passage in a time-sensitive military crisis.

Joel Davis's thorough exploration of maritime security in the Strait highlights the potential of the area as a war risk due to the threat of piracy and terrorism. Davis focuses his analysis on Indonesia, Malaysia, and Singapore and examines the military capabilities of each for maritime security but is mostly concerned with anti-piracy measures and cooperation when dealing with criminal organizations. In addition to discussing the relative military capabilities of each country Davis provides valuable insight into the relationships between the actors in the region and concludes that most of the actors in the region have demonstrated the ability to work together and are all nervous about China to one degree or another.[69] With these considerations in mind, it is important to remember that all straits have an entrance and an exit.

Looking at the other end of the Straits of Malacca indicates that India could have a significant role in any action in the region. Ken Moriyasu of *Nikkei Asia* references the Andaman and Nicobar Islands as "strategically situated" locations that overwatch the Malacca Strait and notes that they have been used to refuel U.S. maritime surveillance aircraft.[70] H. I. Sutton of *Forbes Magazine* concludes that India could certainly block the Straits, although China has begun developing alternate routes around the Straits of

Malacca and is increasing its naval strength in the region.[71] With multiple potential avenues for closure the Straits of Malacca are a key chokepoint in the region, but far from the only potential strategic location to employ land-based fires.

Returning to the 2017 RAND study on land based A2/AD, Ishigaki island represents another potential location due to its proximity to the Senkaku islands and Taiwan.[72] The island has made appearances in regional news on several occasions in this role, with Chheang Vannarith of the Khmer Times referring to it as "a strategic gateway to Asia" due to its access to shipping lanes near Miyako islands. The island has also been the site of increasing amounts of defensive infrastructure including Coast Guard and potentially other Japanese Self-Defense Force facilities.[73] In a more recent article Robert Eldridge notes that the Ishigaki City Assembly has called on the central government of Japan to establish a Japan-Taiwan Basic Relations Act and that the Yaeyama Defense Association has requested the establishment of a Maritime Self-Defense Force base to protect the area.[74]

2461 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Many security concerns in the Indo-Pacific today revolve around the South China Sea, which Marvin Ott described in 2019 as being critical to American interests in terms of critical sea lanes, defense ties with allies and partners, and implications for the global balance of power and influence.[75] Jacob Rosales' monograph from the same year also points out that there are considerable oil and natural gas reserves under the sea floor while pinpointing major Chinese outposts at Fiery Cross, Subi, and Mischief Reef.[76] This builds on and supports earlier work by James Holmes in the *Naval War College Review*, which noted that most of the disputed islands in the region are dependent on outside support and that Chinese vessels moving in or out of the region would most likely transit near the Philippines if not using the Malacca Strait.[77] This indicates that the Philippines should be considered as another location where land-based forces could influence the regional situation.

The 2017 RAND report repeatedly cites the western island of Palawan as a deployment location based on it being within 300 kilometers of the Second Thomas Shoal and within 200 to 300 nautical miles of many other disputed features.[78] The idea of Palawan as a strategic location is a common enough perspective that it has found its way

into nature conservation publications, with a 2021 article describing the island as the country's sentinel in maritime disputes and calling it a jumping off point to the Philippines' Thitu Island base.[79] Based on this information, the MDTF could affect targets within the majority of the South China Sea from this location using its long range fires capabilities. With these three strategic locations identified, the next consideration is the geopolitical climate of the region and how the affected nations view strategic competition between the United States and China.

Broto Wardoyo's examination of Indonesia's perspective on U.S.-China strategic competition argues that Indonesia's concerns in this region are primarily economic in nature. Despite a commitment to reducing tensions in the region Wardoyo highlights the U.S.-Indonesia security relationship and indicates that domestic concerns are the major factor driving these policies.[80] Brian Lenzmeier addressed these factors in his 2019 monograph concerning Indonesian hedging and argues that the U.S. needs to step up its Marine Security Initiatives with Indonesia, strengthen relationships with security assistance and security cooperation, and realign these efforts with other implements of

national power.[81] These studies are based on a relatively stable international situation, and do not anticipate or necessarily apply during a crisis scenario.

Christopher Dibble's 2018 thesis offers a more expansive discussion of these ideas, beginning with describing the history of U.S.-Indonesian relations and then moving on to discuss the principles of Indonesia's maritime framework. One noteworthy portion of Dibble's analysis is that he identifies friction points with China and indications that these might push Indonesia out of its non-aligned status in the face of a severe enough violation. Dibble's thesis primarily focuses on Indonesia's borders, fishing concerns, and piracy.[82] This presents a more nuanced understanding of Indonesia's security and diplomatic considerations, as well as stressing the length and depth of U.S.-Indonesia relations.

The Philippines also has a complicated relationship with the United States and China based on shared history and current security concerns. In 2012 a report from Center for Strategic and Budgetary Assessments described the Philippines as a vital node for U.S. forces in the region, advocating for closer relations with America to check Chinese naval expansion along with assisting the Philippines to develop their own A2/AD capabilities.[83] A more recent report from the Peace Research Institute Oslo shows

that this relationship continues to evolve as China has increased its security and economic ties to the Philippines under president Rodrigo Duterte against the advice of members of the Philippine strategy community while still remaining dependent on the United States.[84]

Richard Hedarian addressed this topic at the beginning of Duterte's term, reporting that Duterte expressed an early desire to reduce dependency on the United States and open ties with China. Hedarian notes that Duterte's actual policy has been more restrained than his rhetoric, but has included restrictions on U.S. operations from the Philippines even as the Philippines struggles to find common ground with China over disputes in the South China Sea.[85] Teresita Ang See's recent work on narratives in Philippine-Chinese relationships provides some important historical context to these relationships, citing common experiences in both countries living under imperial and colonial rule and seeking emancipation.[86] These commonalities and recent changes have complicated the security relationship between the Philippines and the United States, but there is still a high level of cooperation between the two countries and shared concern over Chinese actions in the South China Sea.

A similar but slightly warmer relationship exists between the United States and India. Alexander Mulling's 2019 monograph on the subject describes the Obama administration as recognizing India as a major partner with the intention of developing bilateral security and defense cooperation even though India is primarily concerned with Pakistan despite being wary of China.[87] Andrew Talone echoes these comments by arguing that China is threatening India's sphere of influence in the Indian Ocean region, suggesting that the U.S. and India could affect China by blocking the Malacca Strait or cutting off energy imports despite military limitations would restrict the amount of assistance that India could provide.[88] As a result of this they are in some ways similar to Japan, as Satoru Nagao observed in his proposal for a Japan-India partnership based on both countries having a shared interest in the South China Sea while being partially dependent on the U.S. to counter China.[89]

Muhammad Prabowo provides a recent look at how Japan perceives China in his article in the *Nation State: Journal of International Studies*, claiming that recent tensions over the Senkaku Islands and increasing clashes in the South China Sea have prompted Japan to increase activities and move troops to support their security concerns in the

region.[90] Xuan Tuan Chu contextualizes these views in their 2019 thesis on Japan's engagements in the South China Sea, explaining that Japan views Chinese control over the Spratly Islands as demonstrating their eventual strategy against the Senkaku Islands while at the same time calculating that China being occupied in the South China Sea will prevent such a move.[91] This reinforces the idea that Japan is a key ally for U.S. interests in the region, as well as having an interest in supporting deployment of forces such as the MDTF in pursuit of its own interests.

Sung Keun Hyong's 2018 thesis provides an assessment of Japan's security policy and its impact on U.S. national interests, arguing that Japan is moving toward a more realistic security posture that will see it acting as a more active participant and concluding that Japan's strategy is not detrimental to U.S. interests.[92] In a recent article on Japan's new security posture Taiwan Yamaguchi Noboru refers to bilateral plans to react to Chinese actions toward Taiwan by linking those to the Senkaku Islands, indicating that Japan is working to increase its capabilities for island defenses with long-range stand-off munitions.[93] This is strikingly similar to the concept of using the MDTF

in such a role, further validating the concept and the choice of strategic locations in this study.

Summary

The concept of Multi-Domain Operations has continued to evolve over the last five years, expanding from a basic understanding of the need to compete against peer competitors to an offensively oriented doctrine aimed at overcoming a key adversary capability. Multiple scholars have wrestled with this concept and conceptualized operations in terms of the U.S. perspective concerning China, identifying key terrain in the region and international partners who are intricately connected to those features. There is no escaping the importance of the Indo-Pacific region to U.S. National Security priorities, suggesting that national security professionals should retain a comprehensive perspective concerning potential allies, opportunities, and threats in the area.

While the concept of Multi-Domain Operations has involved since it was first developed as Multi-Domain Battle, there are still significant gaps that must be addressed due to limited engagement from allies, partners, and functional components of the U.S. armed forces. Based on this literature review the primary gaps concern analysis of MDO in the Indo-Pacific region and alternate uses of a Multi-Domain Task Force in an offensive or defensive role. This study will address those gaps and demonstrate how the MDTF can contribute to the Joint Force in the Indo-Pacific.

2468 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 3

RESEARCH METHODOLOGY

Introduction

This chapter will discuss the research methodology, data collection, and data analysis that will be used in Chapter Four and Five to analyze the capabilities of the MDTF, determine what tasks those capabilities allow the MDTF perform, and examine the potential effects the MDTF can generate by conducting those tasks in the Indo-Pacific. This study envisions using the MDTF in a non-standard role to create an A2/AD space through the use land-based fires extending into the maritime domain, integrated electronic warfare, cyber, and space capabilities, and air defense systems. Combined with the MDTF's ability to strike distant targets using long range precision fires, this potentially allows the MDTF to play multiple different roles in potential future conflicts based on occupying key strategic locations. This presents multiple dilemmas to adversaries by influencing their ability to deploy and move troops as well as enabling freedom of movement for U.S. forces in the region.

The primary research question for this study asks how the MDTF can contribute to the Joint Force in the Indo-Pacific outside of its doctrinal mission of penetrating A2/AD spaces. While the MDTF may have been designed for that mission, that does not mean that it lacks the capability to perform other tasks if the capabilities required for its primary mission are used in a creative manner. Examining these capabilities and determining how they can be used in the Indo-Pacific increases the utility of the MDTF in scenarios that do not involve supporting an attack into an A2/AD space, expanding its participation within the range of military operations. This in turn addresses a larger

2469 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

question within military literature concerning the Army's role in the Indo-Pacific. While this study is focused on a single theater of operations, the general principles derived can be adapted for other operating environments in future studies.

The first secondary research question asks what the MDTF's planned capabilities are based on its design documents. This question is necessary because the MDTF was designed to incorporate emerging technologies and has largely been simplified in explanatory literature based on its primary purpose. Due to the narrow focus on the MDTF's role in penetrating A2/AD spaces there has been little thought put into other methods of employing its capabilities since the gap and solution have been so tightly connected. Answering this question requires examining the capabilities of the MDTF in absolute terms divorced from its specific mission, establishing a baseline of how far it can detect, engage, and effect enemies using the full suite of enablers it is intended to have as well as what self-protection capabilities it possesses with organic equipment.

The next secondary research question addresses what operational and tactical tasks that the MDTF can perform based on those capabilities. This includes an examination of the MDTF's role within a decisive action framework, ability to conduct enabling operations, and ability to perform tactical mission tasks as outlined in Army doctrine. These capabilities in turn contribute to the MDTF's ability to participate in joint operations by providing options that can be exercises across the conflict continuum and the range of military operations.[94]

[94] CJCS, JP 3-0, Ch 1, V-8 – V-10.

2470 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The third secondary question asks how these capabilities and associated tasks can be used to shape the operational and strategic environment in the Indo-Pacific. This question applies the answers to the first two questions against key strategic terrain where the MDTF. This demonstrates how the MDTF could potentially operate to generate effects that would affect the operational or strategic situation within the region. Potential areas to explore while answering this question include the possibility that the MDTF could be used to deny passage through key locations, deter adversary action by the threat of being able to strike at disputed territory, or provide coverage to allow movement of U.S. or allied forces to a more advantageous location or to the location of a conflict.

Method

Based on the variety of secondary research questions this study will use multiple qualitative and quantitative methods for research and analysis. The beginning of Chapter Four will examine the differences between the existing MDTF structure, the rough structure outlined in doctrinal documents, and the structure of the MDTF as defined by its requirement documents that list capabilities and components of the MDTF. The most recent requirement documents available will be used to provide a notional outline of what capabilities the MDTF is intended to possess. From there, this study will answer the first and second questions via a reverse-JCIDS analysis. JCIDS, the Joint Capabilities Integration and Development System, is intended to fulfill military requirements by comparing those requirements with existing solutions to identify gaps and then develop

2471 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

solutions to fill those gaps based on the level of risk.[95] Because the solution of the MDTF already exists, reversing the process deconstructs the solution to determine its capabilities and then identifies the gaps that those capabilities can be used to fill.

The first portion of this process is a base level analysis of the doctrinal and organizational requirements for the MDTF, providing a description of the raw capabilities of the MDTF in terms of the systems described within its requirement documents. Once those have been established the second portion of the process examines what gaps those capabilities can potentially fill. To structure this portion of the analysis the MDTF's capabilities will be assessed against the tactical mission tasks listed within ADP 3-90 and further defined in FM 3-90 Volume 1 and 2. The tactical mission tasks that the MDTF is assessed as capable of performing will then be applied against the range of military operations in Joint Publication 3-0.

The results of this analysis will be applied to answer the third secondary question by conducting several small case studies examining the effects of utilizing the MDTF as part of a joint operation in accordance with the tasks it can conduct across the range of military operations. These case studies will begin by overlaying a template based on the range and sensing capabilities of the MDTF over key strategic terrain identified within the literature review to determine the maximum potential area that the MDTF can affect. After defining the area of operations each case study will analyze potential applications of the tasks and capabilities identified in the previous sections to identify how the MDTF

2472 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

could be used during different portions of the range of military operations. A graphical depiction of this method is included as Figure 1.

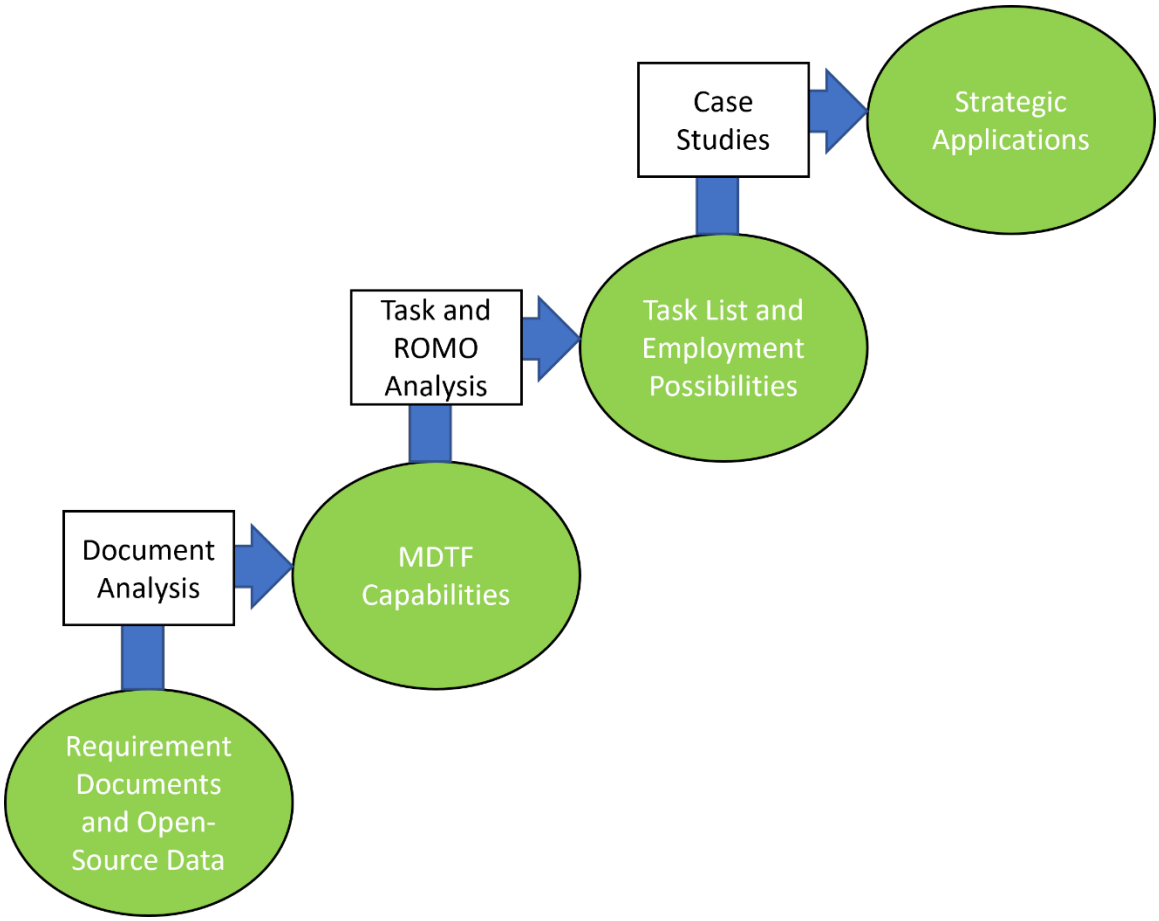

Figure 1. Methodology Diagram

Source: Created by author.

This method is most appropriate because of the requirement for military judgment and non-quantifiable nature of many of the capabilities that will be studied. It would potentially be possible to conduct a mixed methods approach using quantitative methods for the measurable aspects and qualitative descriptions for less concrete data, but the limitation of using non-classified data from publicly available sources and the potential of

2473 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

being unable to locate specific data on all required systems would result in an incomplete comparison. The precise disruptive capability of an offensive cyberspace operation or EW attack cannot be easily calculated in an accessible manner, for instance, while the precise accuracy of a long-range fire system requires detailed testing information that is not likely to be publicly available.

Data Collection

The primary method of data collection will be through analysis of open-source press releases, news reports, country and capability assessments from think tanks such as the Center for Strategic and International Studies or U.S. government databases, technical resources on military equipment. Mission task descriptions, joint operation framework concepts, and requirements documents will use publicly available references or be downloaded from unclassified force structure documentation sources such as FMSWeb for the MDTF's organizations, units, and formations. No restricted, classified, or otherwise non-public data will be collected as part of this study. This data will be screened and filtered to ensure that it is relevant, as recent as possible, and reliable before being used to build a develop a capability list for the MDTF.

Data collection will continue until all publicly announced and potentially applicable long-range fires or integrated air and missile defense systems fielded or in testing for the MDTF have been analyzed. Requirements for the MDTF will be analyzed down to at least the company level for all included units and down to the platoon level in the case of special capabilities such as electronic warfare, cyber defense, or intelligence gathering and target location capabilities. After establishing the range of the MDTF's sensing and fires capabilities, these ranges will be plotted on key strategic terrain

2474 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

identified in the literature review. This will enable analysis of where the MDTF's capabilities could be leveraged in military operations from those locations.

Data Analysis

Answering the first secondary research question will begin by analyzing the Table of Organization and Equipment (TOE) for the MDTF to determine its intended mission, dependencies, employment, capabilities, and functions. Organizational requirements TOEs provide information on the intended structure of a unit and are arranged in a hierarchical fashion with each subordinate unit's TOE providing expanded information on that aspect of the MDTF. This structure continues down to the detachment or company level, where sections, teams, and platoons are broken out in individual paragraphs that describe what that element is intended to provide to the unit. On some rare occasions individual platoons that provide a highly technical capability are also described in their own TOE, often specifically designed for employment by a unique organization such as the MDTF.

While these requirement documents provide information on structure, manpower, personnel, and equipment about the intended capabilities of the MDTF, they do not provide detailed military effects data concerning weapon capabilities. The second part of answering this question will require analysis of open-source data on existing weapons and systems as well as those that are still in development, particularly long-range precision fires and I2EWCS capabilities. Describing the MDTF's capabilities for fires includes data concerning range, magazine capacity, flight speeds, the kinds of targets it can strike and affect, and the ability to mass effects on a target from different ranges. Air and missile defense systems will be described based on detection range, engagement

2475 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

range, and versatility. In terms of this study versatility refers to the ability to engage different types of targets such as cruise missiles, ballistic missiles, and aircraft.

The nature of EW, cyberspace, and space-based capabilities is inherently less measurable and more difficult to compare than long-range fires or air and missile defense systems. Instead, data concerning these capabilities will be assessed for its potential to generate effects on hostile naval and air capabilities or support the use of other systems. Examples of capabilities focused on adversary forces might include the ability to jam, intercept, or interrupt communications, interfering with position-navigation-timing systems, generating false targets or alarms, or remotely shutting down or infiltrating computer systems. Activities in support of friendly activities might include defensive cyber operations to protect partner networks and computer systems, locating targets using overhead imagery or signals intelligence, providing guidance information for weapons systems, or assisting in target identification. These possibilities do not include all possible uses of EW, cyberspace, or space capabilities, and as a result research and analysis may uncover additional possibilities that will be considered during analysis.

To answer the second secondary research question this study will filter the capabilities described in the first research question through the lens of the elements of decisive action and tactical mission tasks described in ADP 3-90. Some elements and tasks will be obviously unsuited for the MDTF and will be identified and discarded at the beginning of this stage of analysis. Detailed information on those tasks is available in FM 3-90 including specific requirements and definitions that allow analysis to determine if a specific unit can conduct the subcomponents of a task. Both actions by friendly forces

2476 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

and effects on enemy forces will be addressed, providing a list of potential tasks that can be assessed against the range of military operations.

As described in JP 3-0 the range of military operations comprises three primary categories ranging from military engagement up to large-scale combat operations along a continuum of conflict from peace to war.[96] Further details on typical operations within each category are provided in separate chapters with employment considerations organized based on the joint operation model. Using these concepts as a backdrop makes it possible to integrate the tasks that the MDTF can accomplish into a joint concept that places its capabilities as part of a construct that includes operational and theater level activities in service of national strategic objectives as part of the Chapter Five.

To answer the third secondary research question, this study will graphically depict the information from the first two questions at key strategic locations identified via the literature review to demonstrate the effective reach of the MDTF. Based on the range of the MDTF's capabilities and the terrain within the area of operations, analysis will focus on how the tasks that the MDTF is capable of can be applied to generate different effects on hostile forces across the range of military operations. The end result of the analysis will discuss how the tasks could be used to generate strategic effects.

Following the collection of all required data this study will summarize the results to answer all secondary research questions to provide an analysis of the MDTF's potential to contribute to joint operations in the Indo-Pacific to answer the primary research question. This analysis will lay out the specific capabilities of the MDTF, the

[96] JCS, JP 3-0, Ch 1, V-4 – V-5.

2477 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

tasks that it can perform, and consolidate the lessons learned from the case studies. The answers to the secondary questions will be used to describe how the MDTF can be integrated into the Joint Operations Model described in JP 5-0 as well as how this recommended integration differs from the existing mission of the MDTF.

Summary

Based on the literature review in Chapter Two, while the question of what role the United States Army can play in the Indo-Pacific theater has been the subject of discussion for some time much of this discussion occurred before the development of the MDTF or has taken the designated mission of the MDTF at face value. As a result, the full potential the MDTF in a future conflict has not been widely studied and there is a gap in our understanding of its intended capabilities and the effects that they can generate against adversary forces. The concentrated firepower, variety of enablers, and long-range sensing and fires capabilities of the MDTF give the unit a disproportionate impact on an operational and strategic level that cannot be fully exploited without thorough analysis of what the unit might be, what tasks it could conduct, and how those tasks can be used to affect the Indo-Pacific theater.

In order to answer the research questions discussed previously this study will use a blended qualitative approach followed by analysis of the resulting data. The first portion of this approach will use a reverse-JCIDS methodology to analyze the MDTF in its role as an existing solution to determine its raw capabilities and the tactical mission tasks it can conduct to determine the gaps it can fill. The second portion of the approach will apply those capabilities and the associated tasks in small case studies based on employment of the MDTF at key strategic locations in the Indo-Pacific using China as a

2478 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

pacing threat. The outcome of those case studies will provide data to answer the primary research question concerning how the MDTF can contribute to the Joint Force in the Indo-Pacific outside of its doctrinally templated mission of penetrating A2/AD spaces.

This method is most appropriate for a variety of reasons, including the non-quantifiable nature of some of the aspects being studied as well as lack of accessible and confirmable numeric data due to classification restrictions. The primary data collection method for this study will be through analysis of open-source documents from a mixture of government, specialist, and media sources. This will include an examination of long-range fires and integrated air and missile defense systems for each country as well as reports on their EW, cyber warfare, and space capabilities. Using publicly available materials does have the drawback of not producing a perfectly accurate representation of the capability being discussed, but the intent of this study is to expand the doctrinal conversation and set the foundation for future development rather than creating a workable operations plan.

While this study focuses on a specific operational environment, the expanded doctrinal role it will support for the MDTF can be adapted to other theaters with appropriate modifications for differences in terrain that create natural barriers to detection and long-range fires. Differences in scale will also affect the role of the MDTF in other theaters, as the widely separated spaces of the Indo-Pacific are in many ways an ideal environment for this unit. Completing those adaptations is a matter of future scholarship, however, and the foundation for that begins now with an examination of what the MDTF is, what it was intended to be, and how it has been described and understood in the past.

2479 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 4

ANALYSIS

The MDTF: Concept, Reality, and Requirements

Before examining the potential roles of the MDTF and how those can be applied in the Indo-Pacific, it is important to first establish what the MDTF is to appropriately evaluate its intended capabilities. This problem is complicated by confusion based on available concept materials, the actual organization as it has been constructed now, and the requirement documents that lay out specific capabilities and equipment sets. No single document can provide an answer to this question, and for the purpose of this study the notional MDTF should include planned future equipment as well as the most current explanations as to what the unit is intended to be capable of accomplishing at is end state as a doctrinal capability. The strongest argument in favor of this approach is that waiting until all required pieces are in places adds a further delay while doctrine catches up to equipment, unit training, exercises, and readiness plans.

Beginning with the depiction of the Multi-Domain Task Force from *Army Multi-Domain Transformation* in Figure 2, we have a broad overview at the battalion and company level. The I2CEWS and Strategic Fires Battalion include breakdowns to the company and battery level but provide no explanation as to what role those companies should play or what terms like "Mid-Range Capability Battery" mean in terms of reach, accuracy, and destructive power. In addition, although this diagram was only published a year ago several of the terms used are out of date and other sources show that all of the MDTF's capabilities are not represented on this diagram.

2480 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

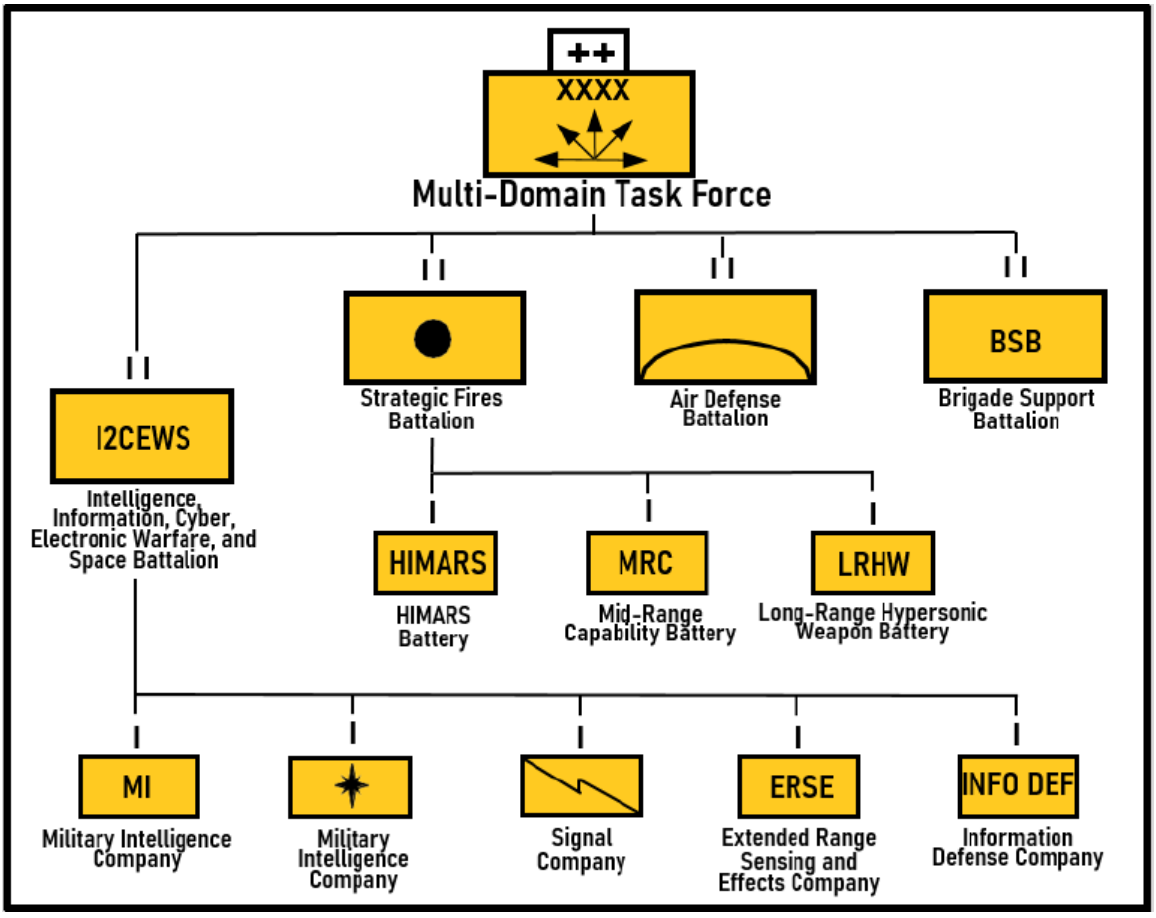

Figure 2. The Multi-Domain Task Force

Source: Headquarters, Department of the Army, "Army Multi-Domain Transformation: Ready to Win in Competition and Conflict," (Chief of Staff Paper #1, Department of the Army, Washington, DC, 2021), 12.

From this starting point it makes sense to examine the actual composition of the Army's most well-established MDTF at Joint-Base Lewis-McChord, but as is so often the case reality does not live up to the vision. Instead, as depicted in Figure 3 below the current MDTF is functioning as a headquarters element that is augmented or has units attached to it for mission or training purposes. The only permanently assigned units are an inactive Indirect Fire Protection Capability (IFPC) Air Defense Artillery battalion, a

2481 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

support company, and a cyber detachment. This is a functional concept for current requirements but does not allow for an accurate representation of future uses and strategic impacts. Currently existing units may be aligned with the MDTF headquarters and expected to be associated or later assigned to the unit on a permanent basis, with 5/3 Field Artillery battalion the most likely candidate as the home of the first Long-Range Hypersonic Weapons Battery.[97]

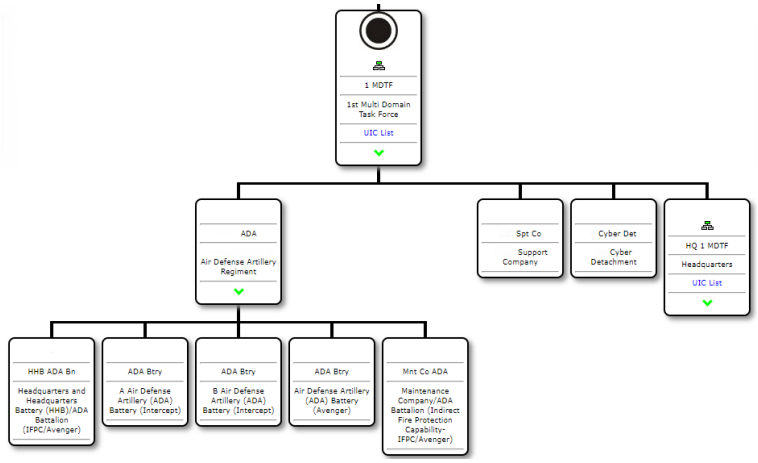

Figure 3. 1st MDTF Line and Block Chart

Source: U.S. Army G3/5/7, "1st Multi Domain Task Force," FMSWeb, accessed 26 February 2022, fmsweb.fms.army.mil.

The next source of information is the most recent Table of Organization and Equipment (TOE) for the MDTF, also drawn from FMSweb. This provides a more complete picture of the intended structure of the MDTF down to the company level, with further detail provided by individual narratives for each assigned unit. This depiction,

[97] Kristen Burroughs, "Dark Eagle is on the Move: Soldiers Complete New Equipment Training," U.S. Army, 14 March 2022, https://www.army.mil/article/254659/dark_eagle_is_on_the_move_soldiers_complete_new_equipment_training.

Figure 4. MDTF Unit Hierarchy

Source: U.S. Army G3/5/7, "MDTF Recap Hierarchy," effective 1 October 2021, FMSWeb, accessed 25 February 2022, fmsweb.fms.army.mil.

While certainly more comprehensive than the previous documents, this information is not as clear as a graphic depiction. In addition, it does not include planned capabilities such as the Mid-Range Capability Battery or Long-Range Hypersonic Weapon Battery. Another noteworthy difference is the inclusion of an attached Gray Eagle UAS Company, which carries important implications for target detection and surveillance capability. This version also differs from the existing line and block chart by

2483 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

including a short-range air defense artillery battalion instead of an IFPC battalion, which provides different defensive capabilities. Combining the planned future systems with this information results in the structure depicted below, with key capabilities that will be analyzed later broken out to the platoon and section level.

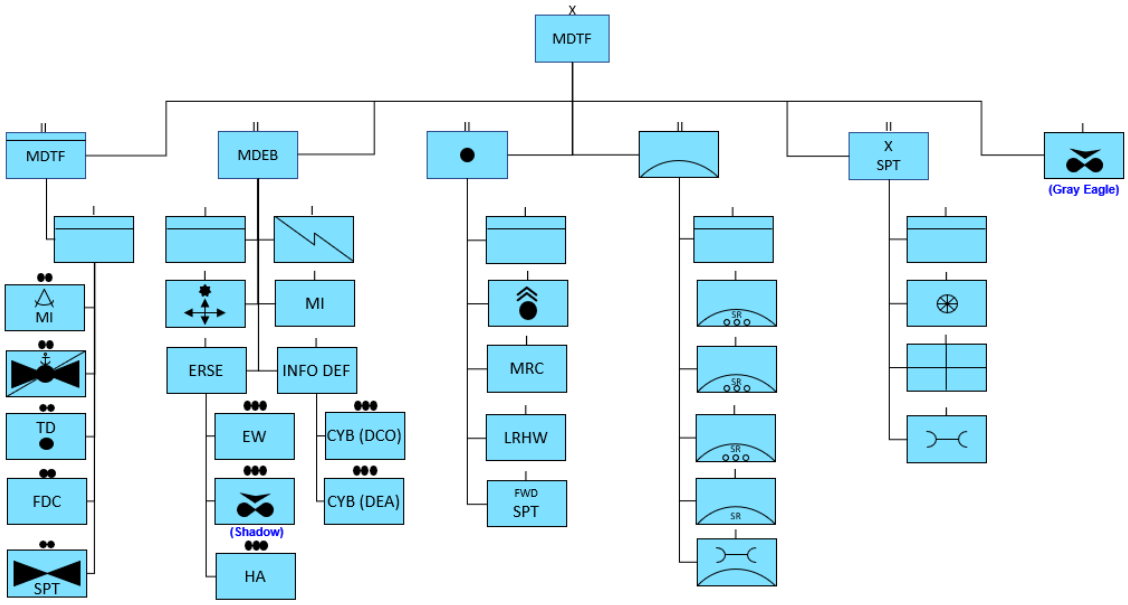

Figure 5. Composite Notional MDTF

Source: Created by author.

Working within this framework it is now possible to begin discussing what these units and capabilities mean in order to build a complete picture of what the MDTF is intended to be and do based on this design. In the next section this study will analyze each battalion and its associated capabilities based on TOE narratives to capture this information. Gaps in information, as in the case of capabilities still in development, will be filled using available sources and publicized results of system tests.

2484 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Intended Capabilities of the MDTF

Headquarters and Overall Purpose

The most recent TOE of the MDTF lays out the formation's purpose in the opening paragraph. Key language for the purpose of this study specifies that the MDTF's mission is "to synchronize and employ fires multi-domain fires (lethal and non-lethal)" to prepare the environment during competition and conduct strikes against enemy A2/AD defenses "to enable joint force freedom of action during conflict."[98] Although this language seems centered around enemy A2/AD defenses, it also specifically says that the MDTF is expected to use both lethal and non-lethal fires during the competition phase of a conflict. This suggests that these fires could be used prior to the establishment of enemy A2/AD defenses. The other important language in this section is that the purpose of the MDTF is to enable joint force freedom of action, which can be read to indicate that while penetration of A2/AD defenses is the primary task of the MDTF that other tasks are acceptable if they meet this overall purpose.

As the rest of the TOE narrative directs the reader to subordinate TOEs for further information, the next source for its capabilities is in the TOE narrative of the MDTF Headquarters Battalion. The capabilities section of the MDTF headquarters TOE claims that it provides twelve capabilities, five of which are relevant to this study: long-range

[98] U.S. Army G3/5/7, "06490K100 Multi-Domain Task Force (MDFT) (Recap) TOE Narrative," effective 1 October 2021, FMSWeb, accessed 25 February 2022, fmsweb.fms.army.mil.

2485 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

fires, air and missile defense, cyber and electronic warfare, surveillance, and space.[99] Broadly speaking long-range fires, surveillance, and space can be grouped together, with long-range fires allowing the MDTF to target critical enemy assets, surveillance including joint and organic targeting against land, maritime, and air domain forces, and space capabilities for situational awareness and position data.[100] These capabilities allow the MDTF to target and attack enemy forces, with the inclusion of naval and air assets providing support for the idea that the MDTF can be used to attack enemy aircraft and ships with appropriate support.

The MDTF's capability for cyber and electronic warfare supports this structure by providing the ability to conduct surveillance in that domain while also providing protection via jamming and defense of tactical network infrastructure. This protective function also includes elements of the MDTF's space capability, which has the capacity to provide early warning of enemy missile attacks. This would seem to connect to the MDTF's capability to provide air and missile defense against ballistic and cruise missiles, hostile aviation, and surveillance, but there is a problem with this listed capability.[101] As designed the MDTF's air and missile defense assets are all short-range air defense weapons, which are unable to detect or engage ballistic missiles. In order to provide defense against ballistic missiles, including detailed information about their probable

[99] U.S. Army G3/5/7, "06492K000 HQ Multi-Domain Task Force (MDFT) TOE Narrative," effective 1 October 2021, FMSWeb, accessed 25 February 2022, fmsweb.fms.army.mil

[100] Ibid.

[101] Ibid.

2486 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

point of impact, the MDTF would need to be augmented with a longer-range system such as the Patriot missile system.

Examining the functions contained within the MDTF headquarters reveals that it contains many of the elements common to any headquarters, but a few capabilities appear unusual and relevant to its mission. Proceeding in order of appearance within the TOE the MDTF headquarters includes a robust intelligence capability that includes a geospatial intelligence cell to enable use of signals, imagery, electronic signature, and other types of intelligence.[102] The MDTF headquarters also includes capabilities related to controlling fires, including a target development element, fire direction center, and fire control element. Other capabilities are focused on interfacing with attached units and temporary capabilities for air and maritime domain capabilities, including an Air Naval Gunfire Liaison Company element as a liaison for joint fires, an air and missile defense team to integrate air defense assets, and an air support element to control aircraft strikes.[103] While some of these inclusions are expected within a fires-centric organization, the combined capabilities indicate that the MDTF is intended to operate independently and have to control a wider variety of assets than a normal brigade-sized artillery element.

[103] Ibid.

2487 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The Multi-Domain Effects Battalion (I2EWCS)

Known as the I2EWCS Battalion in older documents, the Multi-Domain Effects Battalion (MDEB) houses many of the most critical capabilities within the MDTF. This includes the ability to locate targets, conduct defensive cyber operations, receive and process intelligence support, manage space capabilities, and enable communications when conducting dispersed operations. This unit provides subject matter expertise in these capabilities as well as controlling its subordinate signal, military intelligence, space control, extended range sensing and effects (ERSE), and information defense companies.[104] While the battalion's TOE narrative does provide a general purpose for each company, for detailed information on their capabilities it is necessary to examine their individual TOEs. There is no current TOE for the headquarters company, so this analysis will begin with the MDEB's signal company.

The primary purpose of the MDEB signal company is to provide communications elements to ensure access to the Defense Information Systems Network.[105] To fulfill these functions the signal company includes two types of satellite communications teams for secure communications, network extension teams for network connectivity, and troposcatter teams to provide extended range high-frequency communications.[106] Based

[104] U.S. Army G3/5/7, "71495K100 Multi-Domain Effects Battalion (MDEB) TOE Narrative," effective 1 October 2022, FMSWeb, accessed 25 February 2022, fmsweb.fms.army.mil.

[105] U.S. Army G3/5/7, "11497K100 Signal Company, Multi-Domain Effects Battalion (MDEB) MDTF TOE Narrative," effective 1 October 2021, FMSWeb, accessed 25 February 2022, fmsweb.fms.army.mil.

[106] Ibid.

2488 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

on the structure of the TOE the signal company is organized into platoons, each of which includes teams for each capability.[107] This means that the MDTF can support multiple remote locations with redundant communications on top of the organic equipment and communications capabilities within the brigade headquarters.

To add space as a domain capability, the MDEB's space control company is closely tied to its signal company although there is limited information available about this unit and its role due to classification restrictions. The TOE for the space control company indicates that it uses the Mobile Integrated Ground Suite (MIGS) and operates to support satellite communications, coordinate and control space-based effects on designated targets, and provide information on the capabilities of enemy forces.[108] Much like the MDEB signal company, the space control company operates with identical platoons to enable support in multiple locations.[109] Turning to joint doctrine provides some clarity on the purpose of this unit, with Joint Publication 3-14 defining space control as operations to maintain the capability to act in space and prevent efforts to interfere with friendly space capabilities.[110] These capabilities help to ensure that the

MDTF can operate in a contested space environment and conduct missions in multiple locations while adversaries are attempting to prevent use of space-based assets.

The ability to provide information and connectivity is carried over into the MDEB's military intelligence company, which is designed to support multiple command and control nodes according to its TOE narrative. In addition to providing analysis and intelligence preparation of the battlefield, the MDTF military intelligence company includes signals intelligence (SIGINT) teams to support electronic warfare and cyberspace operations and to conduct electronics intelligence (ELINT) to detect non-communications devices that emit into the electromagnetic system such as active radars.[111] While such data is often difficult for non-intelligence personnel to understand, this company also includes a Multi-Domain Processing Exploitation and Dissemination (MD-PED) section with the mission of refining data into usable information.[112] These capabilities contribute to the MDTF's overall ability to detect, locate, and target high-tech platforms on the modern battlefield.

These capabilities are further amplified by the MDEB's Extended Range Sensing and Effects (ERSE) company, which provides detection and electronic warfare capabilities in support of the MDTF. According to the doctrinal mission statement from the ERSE's TOE this unit consists of an unmanned aerial system (UAS) platoon, high-altitude balloon platoon, and electronic warfare platoon with associated sections that

[111] U.S. Army G3/5/7, "34497K100 Military Intelligence Company Multi-Domain Effects Battalion (MDEB) (MDTF) TOE Narrative," effective 1 October 2021, FMSWeb, accessed 25 February 2022, fmsweb.fms.army.mil.

[112] Ibid.

2490 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

provide the capability to detect and attack targets in the electromagnetic spectrum and cyberspace at long ranges.[113] The highly technical nature of these capabilities requires additional exploration, particularly in determining their possible uses and effective ranges. The most straightforward component of the ERSE company is the electronic warfare platoon, which is described across three paragraphs as providing electronic attack, electronic surveillance, and limited cyberspace operations to integrate capabilities and preserve freedom of movement to the MDTF and joint forces.[114]

Two other components of the ERSE company are closely linked: the UAS platoon and the aerial multi-function electronic warfare (MFEW) section. According to the TOE the UAS platoon operates unmanned aircraft for reconnaissance, intelligence, surveillance, and target acquisition (RISTA), communications relay, and persistent surveillance while the MFEW section operates attached systems to support electronic warfare and use electronic attacks to disrupt the enemy.[115]

While the TOE narrative does not specify which unmanned aircraft the platoon operates, doctrinal design and plans for the UAS platoon shows that it is intended to be equipped with the RQ-7B Shadow UAS.[116] The manufacturer's website gives the range of the Shadow as 125 kilometers based on line of sight controls with an endurance of 8 to

[113] U.S. Army G3/5/7, "71490K100 Extended Range Sensing and Effects Company, Multi-Domain Effects Battalion (MDEB) MDTF TOE Narrative," effective 1 October 2022, FMSWeb, accessed 25 February 2022, fmsweb.fms.army.mil.

2491 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

9 hours.[117] A 2020 report on the development of a MFEW system and its use on a RQ-7B Shadow UAS gives a potential detection range of up to 279 kilometers at altitude.[118] Combining these figures gives us a potential detection range of more than 400 kilometers based on a Shadow operating at its maximum potential range.

The ERSE's balloon platoon is less easily defined, with the TOE narrative describing small balloon sections and a large balloon section that are both intended to enable long-range communications, provide RISTA capability, and augment position-navigation-timing data within an area approximately one thousand kilometers across.[119] A 2021 investigation by Adam Kehoe of *The War Zone* provides some insight by identifying recent balloons being tested off the coasts of the United States as derivatives of Raven Aerostar's Thunderhead balloon system.[120]

In his research Kehoe describes two different size variants of the systems operating at altitudes of 60,000 and 92,000 feet, noting that they are designed to act as

2492 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

surveillance and reconnaissance platforms and as communications relays.[121] This matches the TOE doctrinal description, and using a publicly available line of sight calculator for each altitude gives a line of sight of 482 kilometers for the smaller balloon and 597 kilometers for the larger.[122] Based on these figures and the presence of multiple balloon sections, the ERSE also has the capability of deploying a section forward to provide an extended detection envelope.

The final component of the MDEB is the Information Defense Company, which provides incident detection and response functions to protect the MDTF's network Department of Defense Information Network (DODIN) using its defensive cyber operations (DCO) platoon and defensive electronic attack (DEA) platoon and teams.[123] According to the capabilities section of the TOE narrative the former augments cybersecurity capabilities to protect "MDTF networks and mission command capabilities" while the latter are used to provide early warning and active defense against enemy capabilities that use the electromagnetic spectrum such as artillery fuses, rockets and missiles, and unmanned aerial systems.[124] These capabilities are critical to allowing

the MDTF to function in a contested environment and maintain command and control of detachments and subordinate units.

The Strategic Fires Battalion

Describing the strategic fires battalion of the MDTF represents a challenge as the current TOE and the concept for the MDTF are not remotely similar and the latter employs several capabilities and units that are still under development. Currently the TOE for the MDTF is for a High Mobility Artillery Rocket System (HIMARS) battalion with two subordinate HIMARS batteries[125]. The MDTF concept has a single HIMARS battery along with a mid-range capability (MRC) and long-range hypersonic weapon (LRHW) battery. Both versions retain a headquarters battery and a forward support company, while the TOE for the HIMARS battalion provides a functional mission for either unit: "providing medium range rocket and long-range missile fires … to destroy, neutralize, or suppress" enemy forces.[126] For the purpose of this study the MDTF concept will be used with the current doctrinal mission statement, which is versatile enough to allow the strategic fires battalion to be used for multiple roles.

With neither the headquarters nor the forward support company presenting any novel capabilities, the first subordinate unit of interest is the HIMARS battery. The specified capability of this battery is to provide "rocket and missile fires on preplanned targets and targets of opportunity," which is accomplished through the employment of

[125] U.S. Army G3/5/7, "06475K200 Field Artillery Battalion, HIMARS (2x9) TOE Narrative," effective 1 October 2022, FMSWeb, accessed 25 February 2022, fmsweb.fms.army.mil

[126] Ibid.

2494 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

multiple firing sections divided into platoons.[127] According the United States Army Acquisition Support Center each HIMARS launcher can carry a launch pod with six guided rockets or one Army Tactical Missile System (ATACMS), with the guided rockets having a range of more than 70 kilometers.[128] The latest version of the ATACMS, Block 1A unitary, has a range of 300 kilometers and uses a similar warhead to a Harpoon anti-ship missile.[129] Finally, the Army's new Precision Strike Missile (PrSM) is compatible with the HIMARS launcher and contains two rounds per launch pod with a current range of up to 499 kilometers.[130] These options allow the HIMARS battery for the MDTF to be customized for anti-access and area denial missions, and potentially reloaded with increasingly shorter range options as threats approach.

The only existing TOE for a MRC battery does not provide significant information on the capability as most of it is copied directly from the LRHW battery TOE but does indicate that the unit will likely include two firing platoons.[131] Recent

2495 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

reporting on the battery confirms that it will use a combination of land-based SM-6 and Tomahawk missiles with four trailer mounted launchers, implying that each firing platoon would be responsible for two launchers.[132] Each launcher will carry four rounds, providing a total of sixteen missiles for the battery with the ability to reload by replacing an entire missile cell once all rounds have been expended.[133] The exact ranges of these weapons have not been released, but available open source information suggests a range of at least 1,600 kilometers for both the latest variant being developed for the SM-6 and Tomahawk missile.[134] This provides a flexible, extended range anti-access capability that can be used against surface targets including ships.

The final component of the strategic fires battalion is the Long-Range Hypersonic Weapons Battery, which is divided into two firing platoons according to its TOE with a total of eight firing sections that are each responsible for a single launcher.[135] Having been released in 2020 this document may not account for changes in concept, although it

2496 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

would be logical for LRHWs to be larger than other munitions. A more recent Congressional Research Report describes a battery as containing four launchers that are each able to carry two missiles, with an expected range of 1,725 miles (2,776 kilometers) traveling between 3,800 and 13,000 miles per hour.[136] This could potentially allow the LRHW to strike a target at maximum range with a flight times between eight and twenty-seven minutes, enabling convergence with other systems within the strategic fires battalion from multiple directions.[137] One potential consideration with employment of a LHRW battery is that it would likely have to operate detached from the rest of the MDTF as positioning this capability forward could be viewed as escalatory due to its potential ability to strike at targets deep within an adversary's borders.

The Integrated Air and Missile Defense Battalion

For defensive purposes the MDTF includes an air defense battalion to provide short-range air defense (SHORAD) against hostile targets. The current TOE for the MDTF's air defense battalion outlines an organization with a headquarters battery, three Stryker mounted Maneuver SHORAD batteries, a man portable air defense (MANPADS)

[136] Congressional Research Service (CRS), *The U.S. Army's Long-Range Hypersonic Weapon,* CRS In Focus IF 11991, by Andrew Feickert (Washington DC: Library of Congress, 8 December 2021), 1.

[137] Calculated by the author based on a maximum speed up to 13,000 miles per hour and maximum range of 1,725 miles. 13,000 miles per hour equals 216.6 miles per minute. 1,725 divided by 216.6 results in a figure of 7.964 minutes (rounded). A lower-bound of 3,800 miles per hour provides a speed of 63.3 miles per minute and a flight time of 27.25 minutes. Acceleration and deceleration would likely result in a flight time between these extremes.

2497 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

battery, and a specialized maintenance company.[138] Per the unit's TOE the mission and capabilities for this unit are optimized for defense against cruise missiles, unmanned aircraft systems, and low-altitude aircraft, including the use of the Sentinel Air Defense Radar.[139] This is directly counter to the MDTF's mission of providing ballistic missile defense, but still provides a self-defense capability and can provide limited protection over a given area for installations and units.

Briefly examining the systems included, the manufacturer's information sheet for the original version of the Maneuver SHORAD system uses the Stinger and Longbow Hellfire missiles combined with four onboard radars and a 30 millimeter chain-gun to intercept and destroy aerial threats.[140] The Army has recently begun fielding a directed energy capability provided by Northrop Grumman that replaces the missiles on the platform with a high-energy laser to allow for an increased number of engagements.[141] All variants interface with the Sentinel Air Defense Radar, which is capable of detecting targets over 360 degrees at ranges up to 75 kilometers.[142] For an MDTF operating in an

---

[138] U.S. Army G3/5/7, "44315K000 ADA BN (M-SHORAD-MANPADS) TOE Narrative," effective 1 October 2020, FMSWeb, accessed 25 February 2022, fmsweb.fms.army.mil.

2498 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

isolated location this enables a self-defense capability, but the short range of these systems and limited detection range limits the ability of this battalion to an area-denial role rather than presenting a credible anti-access capability.

One potential change to the structure of the MDTF's air defense battalion would be replacing some or all of its Maneuver SHORAD with the Army's Indirect Fire Protection Capability (IFPC) system. This does not change the role of the air defense battalion for the MDTF, however, as the IFPC system is still designed as a short-range capability system for defeating unmanned aircraft systems and cruise missiles.[143]

Another alternative would be assigning or attaching a Patriot missile battery to operate with the MDTF. The new Lower Tier Air and Missile Defense Sensor (LTAMDS) being provided by Raytheon provides 360 degree detection at ranges above 100 kilometers against ballistic missiles, cruise missiles, and fixed-wing aircraft.[144] With a loadout including the Patriot Advanced Capability-2 (PAC-2), this would also enable interception of aircraft at ranges up to 160 kilometers or at the limit of the detection range for the associated radar.[145] This would allow a small anti-access capability for the MDTF while allowing it to meet its stated mission of providing ballistic missile protection. In

2499 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

order to demonstrate this as a possibility, this study will include a Patriot capability during case studies later in this chapter.

The Brigade Support Battalion and Attached Units

The original concept of the MDTF proposed in 2019 included a Brigade Support Company with a distribution platoon, maintenance control platoon, and field maintenance section to receive, store, and issue fuel, manage maintenance stocks, and provide a minimal level of on-site maintenance.[146] This has since been replaced with a full Brigade Support Battalion, including a headquarters, distribution, field maintenance, and medical company to provide the capability to deploy within a 96 hour window and establish operations in an austere location.[147] The individual elements within the Brigade Support Battalion are similar to other examples of these units, although one noteworthy capability is the presence of a missile/electronics repair section, armament repair section, and I2CEWS field maintenance section in the field maintenance company.[148] This demonstrates that these units have been customized to support the MDTF's other capabilities in an expeditionary role.

---

2500 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The final unit assigned to the MDTF is a Gray Eagle Company directly assigned at the brigade level. The current associated TOE for the MDTF-specific version of this unit does not have a TOE narrative, but examining the TOE for a similar stand-alone Gray Eagle Company suggests that such an organization would include its own flight operations section, ground control and launch/recovery sections, and organic maintenance capability.[149] The base model of the Gray Eagle has a flight endurance of over 27 hours at an altitude of up to 25,000 feet, can be controlled via satellite communications, and can carry up to four Hellfire missiles.[150] This allows the MDTF the potential for an unmanned deep-strike capability, but given the amount of firepower resident within the MDTF's strategic fires battalion a more productive use would be locating and providing targeting data for those weapons systems.

According to the manufacturer the next generation of the Gray Eagle intended for Multi-Domain operation provides an extended endurance of up to 42 hours operating at 29,000 feet with a larger payload while retaining the capacity to carry Hellfire missiles.[151] This increases the detection footprint of the Gray Eagle, which Armada International calculates at up to 387 kilometers using a larger version of the Multi-

[149] U.S. Army G3/5/7, "01707K000 Gray Eagle UAS Company (MQ-1C) (SEP) TOE Narrative," effective 1 October 2020, FMSWeb, accessed 25 February 2022, fmsweb.fms.army.mil.

2501 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Function Electronic Warfare capability available to the Shadow UAS platoon discussed earlier.[152] Regardless of which version of the Gray Eagle that the MDTF uses, either platform provides the capability of providing target information out to the limits of the MDTF's MRC battery.

Operating in the Indo-Pacific one useful quality that the Gray Eagle does not currently possess is an anti-submarine capability. This capability is theoretically possible as the Navy has currently fielded a variant of the MQ-9 Reaper that can conduct submarine tracking and detection using a network of sonobuoys dropped by the UAS.[153] Although the MQ-9 Reaper is a significantly larger platform that the Gray Eagle and has a correspondingly higher carrying capacity, a similar system could potentially be developed or modified for use in an MDTF. This would increase the MDTF's ability to conduct intelligence and surveillance operations in the maritime domain and provide early warning for friendly forces.

Doctrinal Requirements and Capabilities Summary

To summarize the overall capabilities based on this analysis, the MDTF's Multi-Domain Effects Battalion provides the ability to locate targets using a variety of methods, conduct defensive cyber operations, receive and process intelligence support, manage space capabilities, and conduct dispersed operations while maintaining communications

[152] Withington, "Small System, Big Difference."

2502 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

in a contested environment. It has an organic electronic warfare capability and the ability to locate targets at ranges of at least 400 kilometers using organic UAS, and the potential to detect targets up to almost 600 kilometers using high-altitude balloons.

The MDTF's Strategic Fires Battalion is intended to include a HIMARS battery, a Mid-Range Capability (MRC) battery, and a Long-Range Hypersonic Weapon (LRHW) Battery. The HIMARS battery has three possible weapons systems with maximum ranges of 70 to 499 kilometers, while the MRC battery uses a combination of land-based cruise missiles and ballistic missiles with a range of up to 1,600 kilometers. The LRHW Battery can provide fires at ranges up to nearly 2,800 kilometers with rounds arriving within minutes of being fired. These capabilities are supported by the MDTF's Gray Eagle Company, which can provide targeting information using over the horizon and satellite-based communications.

Finally, the MDTF is intended to include a short-range air defense capability that is optimized to protect the unit from hostile aircraft, unmanned aerial systems, and cruise missiles. The current TOE for this unit is based on a Maneuver Short Range Air Defense battalion but changing to an Integrated Force Protection Capability does not significantly alter this capability. The MDTF cannot provide ballistic missile defense or extended-range defense against aircraft but could do so if assigned or allocated a Patriot missile battery during operations. These assets can also be used to protect other critical locations and systems in addition to protecting the MDTF, with an accompanying risk of reducing their effectiveness due to reduced depth and mass.

While the MDTF is a very capable unit, it also possesses some operational shortcomings that must be considered when deploying it alone or as part of a group. The

2503 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

first of these is that it is a relatively small unit with limited capability for self-defense against ground assaults. This is mitigated by deployment to islands in the Indo-Pacific and the ability to interdict incoming forces before they can make landfall. The second major shortcoming is that requires a constant supply of fuel and munitions to conduct operations due to the power requirements of radars, UAS, and sensors. This can be mitigated by pre-positioning bulk fuel and logistical planning but could be a factor in extended operations. Third, the MDTF has a relatively small magazine depth of only 18 Precision Strike Missiles, 16 rounds in the Mid-Range Capability battery, and 8 rounds for the Long Range Hypersonic Weapon battery. This limits the number of targets it can strike before conducting reload operations and requires a substantial ammunition storage facility for extended operations.

It is also important to consider the fact that some of these capabilities are currently in development or in limited rate production. The Army's first Long Range Hypersonic Weapon battery is not expected to reach initial operating capability until fiscal year 2023.[154] The Precision Strike Missile is currently in production, with the Fiscal Year 2022 Army Budget requesting production of 110 rounds for the first year.[155] According to Major General Ken Kamper's speech at the Maneuver Warfighter Conference on 7 March 2022, the next upgrade to the Precision Strike Missile to allow it

[155] Office of the Under Secretary of Defense (Comptroller)/Chief Financial Officer, *Program Acquisition Costs by Weapon System,* U.S. Department of Defense Fiscal Year 2022 Budget Request (Washington, DC: Department of Defense, May 2021), 5-15.

2504 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to target moving emitters such as ships is not expected to be complete until 2025.[156] Keeping the current status of these capabilities in mind and planning for future operations, the next step is to examine them with an operational framework.

Capabilities, Gaps, and Applications

Tactical Mission Tasks

Although not an exhaustive list, the Army's list of tactical mission tasks provides a framework that assists in describing the desired action that a force will take and the intended effect that action will have on an enemy. Examining this list considering the established capabilities of the MDTF provides the foundation to conceptualize how the MDTF can be used in operations supporting the joint force. In addition to the table below, tactical shaping tasks including reconnaissance and security operations can also provide clarity on the potential for multiple roles for the MDTF.

[156] Ken Kamper, "Fires Modernization," (Speech, Maneuver Warfighter Conference, Fort Benning, GA, 7 March 2022), https://www.youtube.com/watch?v=RuZxEbWV7s8.

Figure 6. Tactical Mission Tasks

Source: Headquarters, Department of the Army, Field Manual 3-90-1, Change 2, *Offense and Defense,* vol. 1 (Washington, DC: Army Publishing Directorate, March 2013), B-1.

The basic task of the MDTF can be viewed as a combination of attack by fire in support of a larger breaching operation, acting as part of the means to break through an enemy defense for follow-on forces to maneuver as part of Multi-Domain Operations. A number of tasks in the figure above require a degree of movement and direct fires that the MDTF is not constructed to provide, including bypass, clear, disengage, exfiltrate, follow and assume, follow and support, and seize. This leaves seven additional tasks where the capabilities of the MDTF are open to interpretation.

The first of these, control, is defined as "maintaining physical influence over a specific area to prevent its use by the enemy or create conditions necessary for successful friendly operations" by either occupying the area or being able to engage enemy forces

2506 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

within the area.[157] In the conventional sense this is usually conducted by ground forces, but given its ability to engage surface targets at extended range using a variety of weapons the MDTF could perform this activity in a maritime environment. The effectiveness of control that the MDTF can provide increases as the volume to be controlled shrinks, allowing the MDTF to apply more weapon systems within the area. This is closely linked to the task of counterreconnaisance, which "encompasses all measures to counter enemy reconnaissance and surveillance efforts" as a fundamental part of security operations.[158] By preventing enemy use of an area the MDTF also prevents enemy forces from effectively locating friendly assets moving through the area.

A similar relationship exists between the tasks of occupy, retain, and secure. Occupy involves "moving a friendly force into an area so that it can control that area" without being opposed by an enemy and is different from control because it requires physical presence at a location.[159] Retain focuses on keeping "a terrain feature controlled by friendly forces from enemy occupation or use" but does not require the unit to occupy the area. Secure requires keeping an enemy from damaging or destroying a unit or location and can also be done without occupying the terrain to be secured as long as the force can keep the enemy from affecting it.[160] The MDTF can occupy terrain to a limited

---

[159] Ibid., Ch 2, B-9.

[160] Ibid.

2507 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

extent and may be able to retain a location using its long-ranged fires by preventing enemy forces from moving onto a location. The extensive range of the MDTF's capabilities and electronic warfare capabilities may also enable it to secure a location by keeping enemy forces outside of direct or even indirect fire range, but this is limited to air and surface forces within a given radius and does not apply to long-range ballistic missile attacks.

The final two tasks are subject to debate. Reduce is a "the destruction of an encircled or bypassed enemy force,"[161] while support by fire is when a unit "moves to a position where it can engage the enemy by direct fire in support of another maneuvering force" to fix, suppress, or destroy the enemy if they attempt to move.[162] Theoretically an MDTF could be used as the primary instrument to destroy an enemy force using massed fires, but this would likely require a prodigious expenditure of ammunition to accomplish a task that could likely be easily managed by a less specialized capability. The specification of direct fire as the means of accomplishing support by fire makes the MDTF unsuited to the task, although the MDTF could potentially produce the desired effect of suppressing, fixing, or destroying an enemy force trying to reposition.

The second half of the figure at the beginning of this section addresses effects on the enemy, which provides additional utility for discussing employing the MDTF. Effects based language is more general and allows for a freer rein in analysis, with only two of the listed effects appearing immediately unsuited to the capabilities of the MDTF.

2508 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Contain and fix are both tasks that involve controlling the movement enemy forces, with the former requiring a capability to "stop, hold, or surround enemy forces"[163] while the latter requires preventing an enemy "from moving any part of their force from a specific location."[164] Both of these tasks are extremely difficult to accomplish with long-ranged fires and electronic warfare assets, as they typically involve some form of direct contact to control enemy movement.

Other movement controlling tasks are more clearly within the capabilities of the MDTF, especially when operating in a maritime environment. Block and canalize are two examples based on imposing an unacceptable cost for proceeding on an avenue of approach or restricting enemy movement to a confined area using fires or maneuver.[165] Both of these effects can be accomplished by using progressively heavier fires to attrit an enemy force or to force an enemy to stay outside of engagement range and thus limiting their number of available routes. This is closely related to turn, which "involves forcing an enemy element from one avenue of approach or mobility corridor to another."[166] In a maritime dominated environment the MDTF can accomplish this task by using fires to engage an enemy when they attempt to use an undesired avenue of approach and thus force them into using a slower or more dangerous route.

[165] Ibid., B-11.

[166] Ibid., B-15.

2509 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Other effects that the MDTF can accomplish are based on their impact on enemy operations. Disrupt involves efforts that "upset an enemy's formation or tempo, [or] interrupt the enemy's timetable"[167] while interdict "prevents, disrupts, or delays the enemy's use of an area or route."[168] Neutralize and suppress prevent an enemy from interfering with friendly activities or accomplishing their own mission and can both be accomplished through lethal and non-lethal effects such as electronic warfare.[169] The ability to detect targets at long ranges and place accurate fires as well as the capability to generate electronic attack within the multi-domain effects battalion make the MDTF uniquely well-suited for generating these effects and degrading or shaping enemy operations.

The final category of effects to consider in relation to the MDTF are effects directly targeted at enemy forces. Defeat includes rendering an enemy unable or unwilling to fight through force or threats of force[170] while destroy "physically renders an enemy force combat ineffective."[171] Isolate requires preventing an enemy from receiving support, denying their ability to move, and preventing them from contacting other forces.[172] The first two are within the MDTF's range of capabilities depending on the

[172] Ibid., B-14.

2510 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

amount of firepower applied, with the task of rendering a naval combat system ineffective particularly well-suited to the MDFT's Mid-Range Capability. Isolation is also theoretically possible since electronic warfare capabilities can be used to prevent contact while fires can target incoming support and deny freedom of movement.

Turning to reconnaissance and security, reconnaissance squadrons and air cavalry forces are doctrinally described as capable of conducting route, zone, or area reconnaissance.[173] The reconnaissance and detection capabilities of the MDTF suggest that it can also conduct these activities, although this is a situational capability as other forces might be better suited to these roles. When operating independently ahead of friendly forces, however, the MDTF could provide initial reconnaissance before other assets are able to arrive.

Combining the tasks and effects that the MDTF can generate also indicates that it could conduct security operations, particularly a screen or advance guard. The doctrinal definition of a screen includes providing early warning while a guard fights to protect the main body, gathers information, and prevents enemies from observing or firing on friendly forces.[174] The advanced reconnaissance and electronic warfare capabilities of the MDTF enable it to provide early warning in a maritime environment while its fires can slow enemy movement to gain time and be used to keep enemy forces out of firing range of other forces as they move through the area it controls.

---

[173] Headquarters, Department of the Army (HQDA), Field Manual (FM) 3-90-2, *Reconnaissance, Security, and Tactical Enabling Tasks,* vol. 2 (Washington, DC: Army Publishing Directorate, March 2013), 1-6.

[174] Ibid., 2-1.

2511 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The Range of Military Operations

Armed with the list of potential tasks and effects that the MDTF can employ, the next step is to integrate those within the range of military operations. Most defense professionals are familiar with this construct as depicted below showing notional operations across the conflict continuum. The MDTF and its capabilities, tasks, and the effects that it can generate have a role across the entirety of the conflict continuum.

Figure 7. The Range of Military Operations

Source: Office of the Chairman of the Joint Chiefs of Staff, Joint Publication 3-0, Change 1, *Joint Operations* (Washington, DC: The Joint Chiefs of Staff, October 2018), V-4.

The Department of Defense defines military engagement as "routine contact and interaction" between the United States military and the armed forces and civil authorities of another nation, while security cooperation specifically applies to interactions with foreign defense establishments for purposes such as developing their military capabilities and establishing access.[175] The MDTF has no special capabilities that apply to these

[175] CJCS, JP 3-0, Ch 1, VI-3.

2512 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

aspects of the conflict continuum, although it can conduct security cooperation through joint training or exercises and needs established access in order to be effective in situations higher up the continuum. Other units such as Security Force Assistance Brigades or Special Operations Forces are better suited to security cooperation efforts aimed at building capacity, while the MDTF provides a greater deterrent capability.

JP 3-0 describes deterrence as "preventing adversary action through the presentation of a credible threat of unacceptable counteraction" and notes that forces that cannot conduct decisive operations should be prepared to defend themselves while waiting for support.[176] The MDTF's long-range capabilities and ability to locate targets present a credible threat to surface forces attempting to interfere in an area where the MDTF is deployed, either through attacks on facilities or on forces attempting to conduct unwelcome operations. Within joint doctrine these activities can be conceived as a type of show of force or protection of shipping operation. The MDTF's ability to disrupt and interdict forces moving into an area suggest that it would also be able to fulfill the requirement of conducting defensive operations while additional forces move into the region and protect those forces while they are in-route.

The capacity to deter hostile forces is also relevant in crisis response and limited contingency operations further up the conflict continuum. Joint doctrine describes initial response to these situations as deterring aggression and signaling commitment while taking economy of force into consideration.[177] As a relatively small force with an

[176] CJCS, JP 3-0, Ch 1, VI-4.

[177] Ibid., VII-1 – VII-2.

2513 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

outsized impact due to the amount of firepower it includes and variety of IC2EWS effects it can generate, the MDTF has considerable potential as an initial response force. This is also supported by its expeditionary capability and ability to quickly establish itself in an austere environment.

Typical examples of contingency and crisis operations include noncombatant evacuation operations, peace operations, foreign humanitarian assistance, recovery operations, strikes, and raids.[178] The MDTF is generally ill-suited for most evacuation, peace, and humanitarian operations, although its signal detection and surveillance activities could prove useful during personnel recovery operations in concert with other forces. The MDTF's long-range fires are ideal for locating targets and launching strikes from a distance, but as a raid requires seizing an area the MDTF would have to operate in a supporting role for such a mission.

At the highest levels of the conflict continuum in large-scale combat operations the MDTF would fulfill its primary function once conflict begins, but there are several relevant areas in setting conditions for theater operations where the MDTF can also play an expanded early role. Joint doctrine for large-scale combat operations stresses the importance of maintaining operational access, isolating the enemy, executing flexible deterrent options (FDOs) or flexible response operations (FROs), control of littoral areas, and the difference between opposed and unopposed deployment operations. [179] Unopposed deployment operations are considered preferable as they provide a more

[178] CJCS, JP 3-0, Ch 1, VII-2 – VII-4.

[179] Ibid., VIII-5 – VIII-12.

2514 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

flexible environment, while opposed deployment operations take place in the context of having to deal with enemy A2/AD establishments.[180]

The intended role for the MDTF is in conducting an opposed deployment but based on the capabilities outlined previously early deployment of an MDTF can enable it to contribute to other aspects of setting the theater. This is particularly true in a maritime environment, where an MDTF deployed on key terrain could control enemy access to a space to maintain operational access for friendly forces by controlling littoral areas using shore-based fires. Taking the initiative by deploying the MDTF in this role can turn a potentially opposed entry into an unopposed entry. The MDTF can also be used to isolate potentially hostile forces based on an island by interdicting support using long-range fires or use its electronic warfare capabilities to suppress communication capabilities. Previous discussion on the MDTF as a deterrent show that it can serve as part of a flexible deterrent option with the added capability of acting as a flexible response on command.

Key Terrain and Case Studies

Before launching into individual cases where the MDTF might be utilized in the Indo-Pacific to illustrate its capabilities and the tasks it can conduct overlaid on terrain it is important to set the parameters for the illustrations below. The extreme range of the Long-Range Hypersonic Weapons battery means that in the roles the MDTF will fill in the scenarios below it cannot be collocated with the rest of the unit. There are potentially friendly locations where it can be placed with the ability to range targets within the rest of the MDTF's area of influence for each scenario below. While operational considerations

[180] CJCS, JP 3-0, Ch 1, VIII-12.

2515 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

would dictate the actual positioning of this unit during an operation, example locations can be found in the illustrations section at the end of this thesis.

All scenarios included below depict the range of the Mid-Range Capability battery, the maximum range of the HIMARS battery, and the range of a PAC-2 missile depicted as red range rings. The latter is included for illustration purposes even though the MDTF does not have an organic capability to conduct long-range air defense operations. Blue rings illustrate the maximum detection range of the Shadow UAS and the maximum calculated detection range of the high-altitude balloon capability from the Multi-Domain Effects Battalion. The detection range of the Gray Eagle is not included on these diagrams as the system's range, endurance, and over-the-horizon communications capability allow it to range to the full extent of the Mid-Range Capability battery. Selection of a surveillance area would be mission-dependent and focus on surveillance of key avenues of approach detailed in the scenario.

The Senkaku Islands, Taiwan, and Ishigaki

Located west of Okinawa, the Senkaku islands have long been an area of contention between China and Japan as discussed in Chapter Two. The islands are uninhabited but are located near shipping routes, surrounded by fish, and may have reserves of oil and gas.[181] The remote location of the islands has resulted in confrontations over the disputed territory historically involving naval confrontations or air incursions. One of the largest nearby islands that could potentially host a MDTF in the

[181] Center for Preventive Action, "Tensions in the East China Sea," Global Conflict Tracker, Council on Foreign Relations, accessed 15 March 2022, https://www.cfr.org/global-conflict-tracker/conflict/tensions-east-china-sea.

2516 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

event that the United States intended to deter activity in the area of deploy forces in a crisis is Ishigaki island, located east of Taiwan. The figure below depicts the range of MDTF weapon and surveillance systems if deployed to Ishigaki.

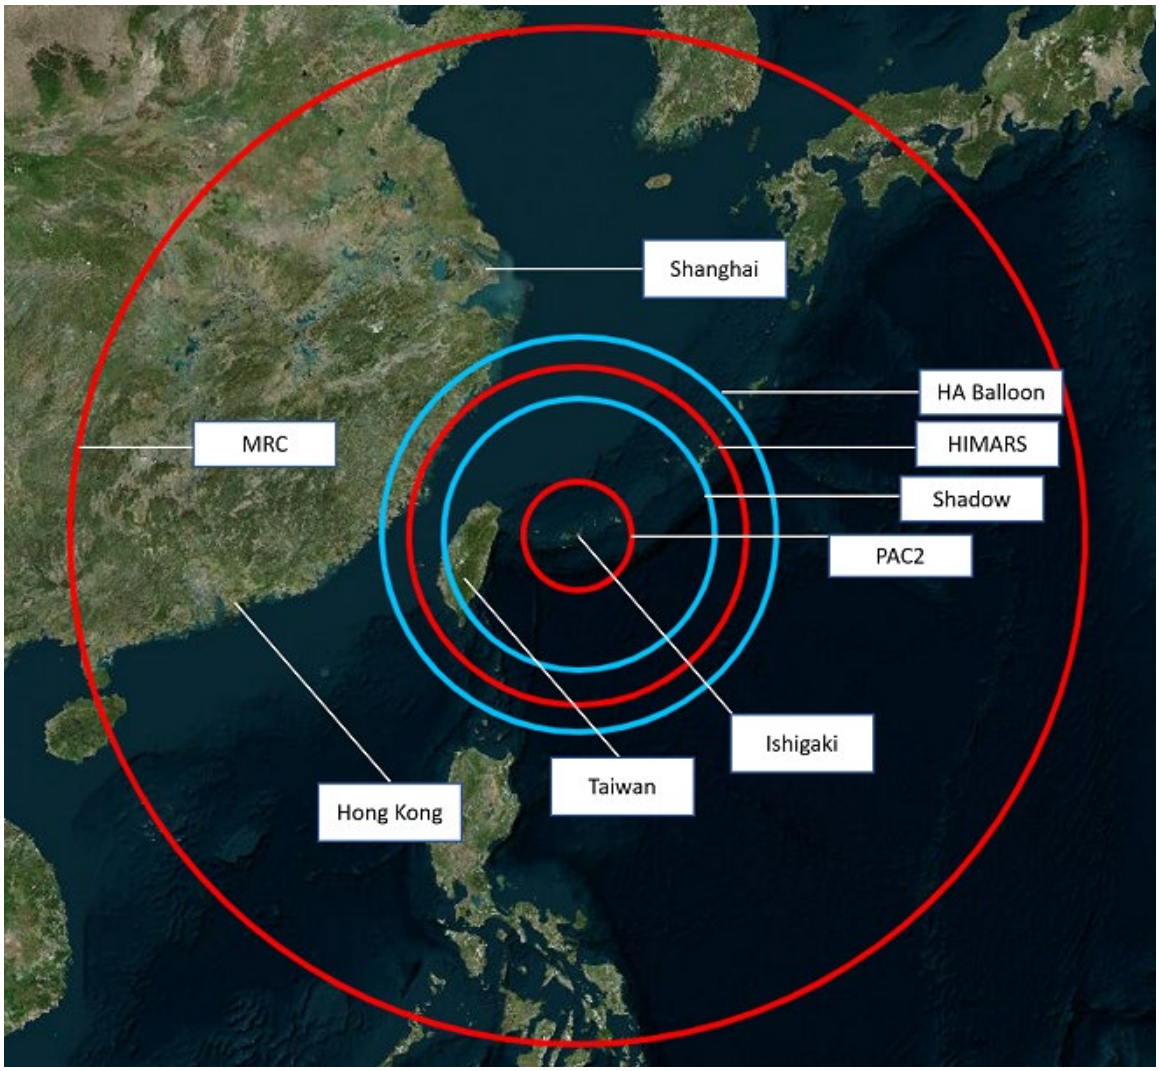

Figure 8. The MDTF on Ishigaki

Source: Created by author using map from DigitalGlobe, "Maxar, Global Enhanced GEOINT Delivery," accessed 15 March 2022, G-EGD Login (digitalglobe.com).

2517 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

From this location the MDTF can use its surveillance and detection capabilities to cover the entirety of the disputed region as well as being able to identify and track aircraft and ships departing China's coast adjacent to the Senkaku Islands. The MDTF's Mid-Range Capability battery can provide anti-access capabilities against ships transiting through the South China Sea using the Gray Eagle's surveillance capability. Using the HIMARS to its maximum range also allows the MDTF to conduct area denial operations to deny freedom of movement past the coastline of China and to the south once potential targets pass between Taiwan and the Philippines.

Based on the tasks that the MDTF has been identified as being capable of conducting, this placement allows it to control the region surrounding Ishigaki and retain the Senkaku islands by disrupting naval forces enroute to that location. Deployed as a deterrent, the range of its weapon systems allow it to transition to a response posture and conduct attacks on key port facilities in the region or interdict forces moving into the region. Because the MDTF can control the area between Taiwan and Okinawa from its location on Ishigaki, this also allows it to provide security for naval forces moving south from ports in Japan. This has the potential to allow allied naval forces to proceed much closer to the Chinese coast without coming under direct attack from hostile ships operating in the East China Sea.

In addition to the ability to act in response to a dispute in the Senkaku islands, positioning the MDTF on Ishigaki also places the entirety of Taiwan and most of the Taiwan Strait within the MDTF's area of influence. Although the United States has followed a strategy of deliberate ambiguity on the question of whether it would intervene in the event of a conflict over possession of Taiwan, in such an event an MDTF located

2518 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

on Ishigaki could use forward surveillance assets to disrupt or interdict an attack on Taiwan. As a result, the presence of an MDTF on Ishigaki during the leadup to a possible conflict could serve as a formidable deterrent. If the United States were unwilling to intervene directly, the surveillance capabilities of the MDTF could still be used to provide intelligence to Taiwan or to other partners within the region.

Palawan, the Spratlys, and the South China Sea

Another hotly disputed region in the Indo-Pacific is the South China Sea, with almost all surrounding nations submitting competing claims for islands, shoals, and the natural resources surrounding them in the shallow waters of the region. This has been of particular concern with the Spratly Islands, which lie within a disputed area between the Philippines and China, and the Paracel Islands which China has increasingly used as a base of operations. Historically close ties and a mutual defense treaty with the Philippines raise the possibility that the United States could become involved if the dispute escalates.[182] As discussed in Chapter Two of this thesis, in such an event the island of Palawan southwest of Luzon could serve as an important strategic location for deployment of an MDTF as depicted in the figure below.

[182] Center for Preventive Action, "Territorial Disputes in the South China Sea," Global Conflict Tracker, Council on Foreign Relations, accessed 15 March 2022, https://www.cfr.org/global-conflict-tracker/conflict/territorial-disputes-south-china-sea.

2519 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

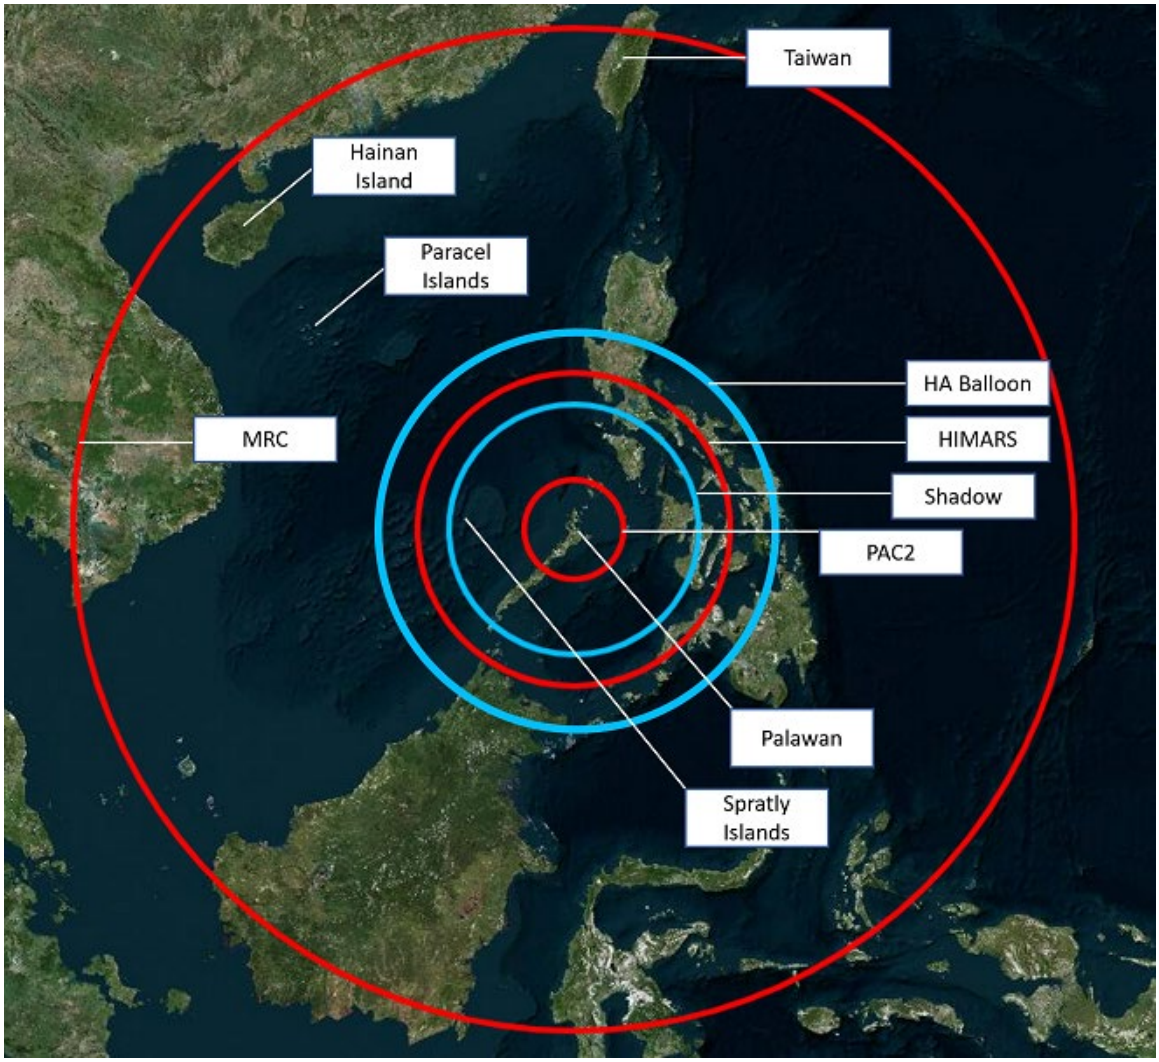

Figure 9. The MDTF on Palawan

Source: Created by author using map from DigitalGlobe, "Maxar, Global Enhanced GEOINT Delivery," accessed 15 March 2022, G-EGD Login (digitalglobe.com).

From a position on northern Palawan, the MDTF has the ability to detect and target forces moving throughout the majority of the Spratly Islands. The bulk of the islands are within range of the MDTF's HIMARS fires, enabling area denial activities to restrict enemy movement in the waters around the islands. The Mid-Range Capability battery can deny access from the south and around both sides of Taiwan to the north. It

2520 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

can also range the Paracel Islands to the northwest and reach ports on the coast of China. The number of potential avenues of approach and potential targets has the potential to stretch the MDTF's Gray Eagle company to its limits, requiring careful selection of surveillance locations to enable continuous operations.

From a task-based perspective, the MDTF has multiple potential roles to play from this location. Its proximity to the Spratly Islands enables it to control the space around them, as well as being able to secure Palawan and the nearby islands by preventing enemy forces from approaching within firing range. The MDTF also has the capability to interdict movements into the South China Sea from either direction or disrupt operations originating from the Paracels or the coast to the north. This enables it to potentially isolate forward bases such as Woody Island in the Paracels through long-range fires and electronic warfare. Finally, the MDTF's control of the southeastern approach through the Philippines protects an avenue of approach for U.S. and allied forces as well as a protected location to stage for follow-on operations.

The Malacca Strait

The previous two examples have focused on the MDTF's potential roles in controlling access and movement within a designated area. The final example examines the capability of the MDTF to interdict movement through a key waterway: the Malacca Strait. As the most direct route between the Indian Ocean and the South China Sea the Malacca Strait is one of the busiest waterways in the world while at the same time being extremely narrow and shallow throughout most of its length.

This makes it particularly susceptible to land or sea-based control, with the long-range fires of the MDTF allowing it to subject incoming forces to an increasing volume

2521 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of fire as they continue onward. This can serve to either block enemy forces or turn them and force them into a more distant passage, substantially delaying China's ability to mass forces by moving ships from the Indian Ocean to the South China Sea and vice-versa. The geography of the Malacca Strait allows for several options to deny passage, with the first depicted in the figure below.

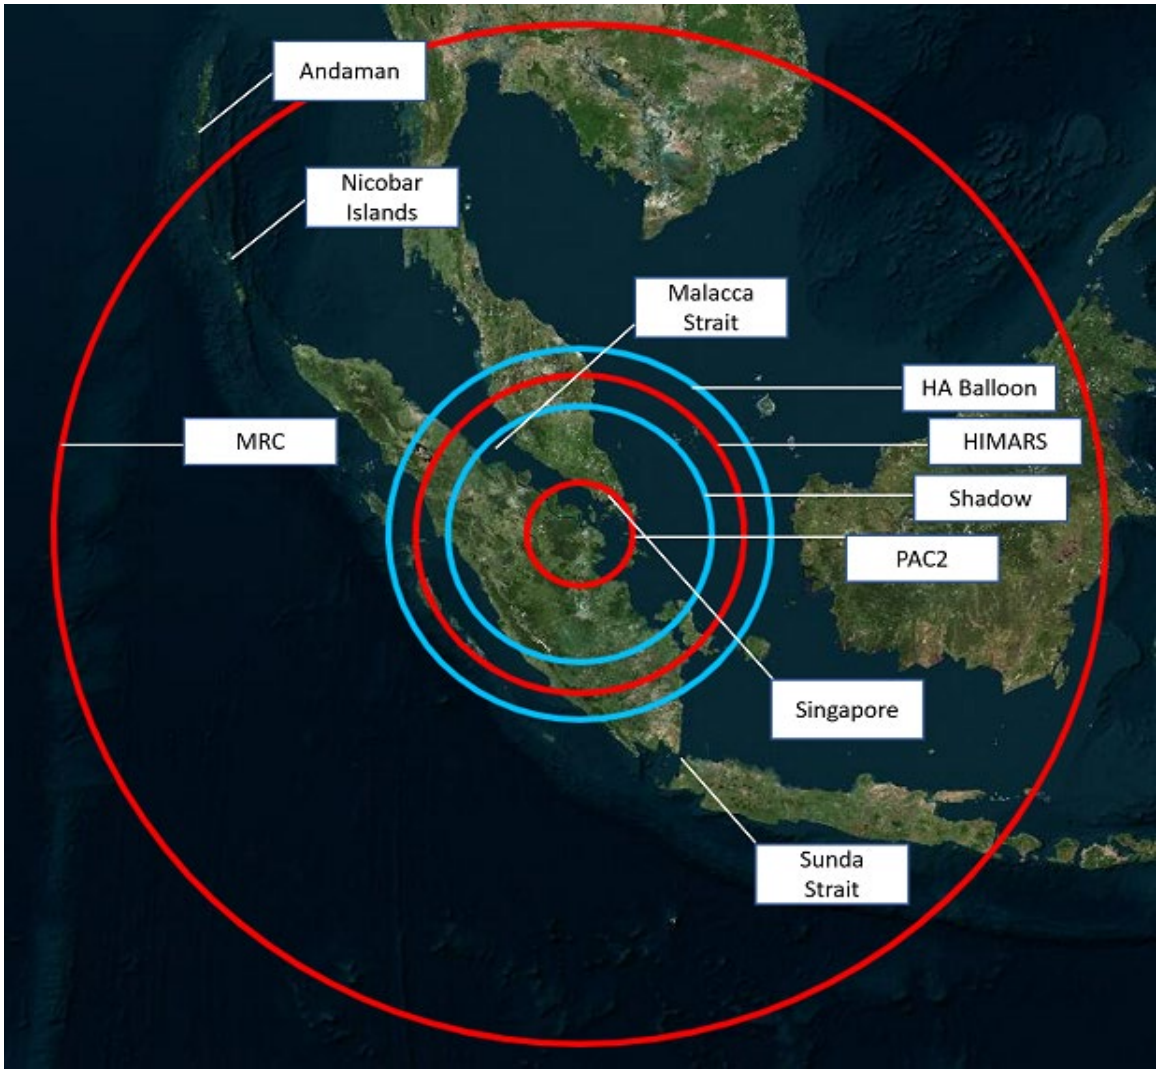

Figure 10. The MDTF in the Malacca Strait

2522 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In this example the MDTF is positioned in Sumatra, although the confined terrain within the Malacca Strait would allow a similar effect operating from Malaysia or Singapore. This increases the flexibility of this option by allowing for multiple deployment locations dependent on the currents of international relations. Regardless of the location used, this position provides superior area denial within the Strait while retaining the ability to deny access from either direction through the South China Sea or the Indian Ocean. In addition to denying access to the Malacca Strait, an MDTF positioned near this location can also deny access to the Sunda Strait between Java and Sumatra. This compounds the delay created by denying access to the Malacca Strait, effectively preventing China from combining its naval forces across the region in response to a crisis on either side of the Strait and enabling the U.S. and allied forces to obtain local superiority.

2523 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

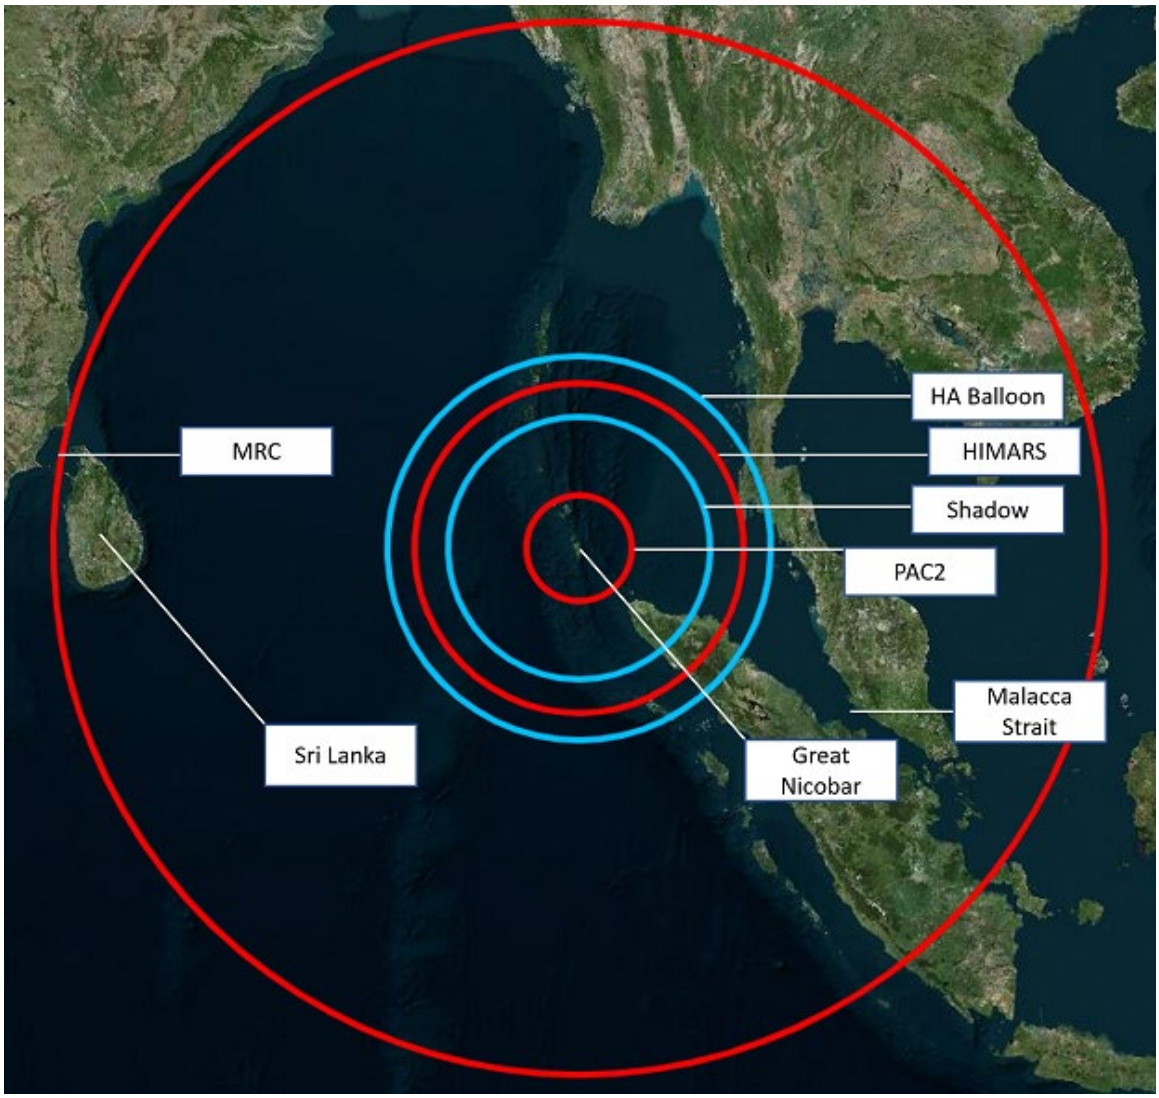

Figure 11. The MDTF on Nicobar

Source: Created by author using map from DigitalGlobe, "Maxar, Global Enhanced GEOINT Delivery," accessed 15 March 2022, G-EGD Login (digitalglobe.com).

The second alternative depicted in the figure above places the MDTF on Great Nicobar Island. This extends the anti-access capability to the east at the expense of losing the ability to block routes through the South China Sea and Sunda Strait. It retains the ability to deny access throughout the Malacca Strait while providing increased area denial

2524 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

capability at the mouth of the Strait to strengthen the ability to turn naval forces and drive them to another route. By limiting the number of avenues of approach that the MDTF must cover this positioning also conserves reconnaissance and surveillance assets, increasing their endurance. In this case the duration of the delay imposed by controlling the Malacca Strait from this end is reduced in exchange for a greater probability of success. This deployment is more suited for an attempt to delay Chinese forces in the Indian Ocean from reaching the South China Sea than the reverse, which may be a more effective response based on the level of emphasis placed on the respective regions.

This chapter has analyzed the MDTF based on the requirement documents establishing the capabilities defined for each subordinate element by using open-source information to define the exact ranges and roles of each significant section. After defining the MDTF based on its capabilities the analysis proceeded to put these capabilities against the Army's menu of tasks and effects to show how the MDTF can support the joint force beyond its intended role in penetrating A2/AD spaces. Finally, by templating the MDTF against terrain in the Indo-Pacific this chapter demonstrates how the MDTF can be used in a variety of situations to provide examples of situations where the MDTF could fulfill these new roles. In the concluding chapter, this study will summarize the conclusions from this research and provide recommendations to the force and areas for further study.

2525 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 5

CONCLUSIONS AND RECOMMENDATIONS

Conclusion: How the MDTF Can Contribute to the Joint Force

To frame the conclusion of this study, the most efficient method is to return to the secondary and primary research questions established in the first chapter beginning with the secondary questions and concluding with the primary question. The first secondary research question asked what the planned future capabilities of the MDTF are based on its design structure. The second secondary research question asks what tasks the MDTF can accomplish outside of its existing doctrinal mission as an A2/AD piercing formation based on those capabilities. The third secondary research question asks how the MDTF's capabilities and the tasks it can perform can be used to shape the operational and strategic environment in the Indo-Pacific. This ties directly into the primary research question, which asks how the MDTF can contribute to the Joint Force in the Indo-Pacific beyond penetrating A2/AD spaces.

Beginning with the first secondary research question, based on the analysis in Chapter Four the MDTF's planned capabilities include the ability to deploy and operate in an austere environment and operate dispersed in at least three locations. The MDTF's organic components provide the capability to detect targets at ranges up to approximately 600 kilometers using signal and electronic intelligence, as well as two types of UAS that can operate on a line-of-sight basis with a detection capability of over 400 kilometers and an over the horizon capability that is only limited by the endurance of the UAS platform. These UAS have a detection footprint of 279 kilometers and 387 kilometers from the

2526 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

location of the platform itself, allowing the two types of UAS to cover more than 240,000 and 470,000 square kilometers of surface area for each operating platform.

The MDTF is also equipped to maintain satellite and network communications in a contested operational environment and to answer with its own electronic warfare capability. The layered fires capabilities within the MDTF allow it to engage targets simultaneously with three weapons systems at ranges of up to 500 kilometers, two weapons systems out to 1600 kilometers, and up to 2750 kilometers with its Long Range Hypersonic Weapon battery. It does not possess an organic capability to defend against ballistic missiles but has a self-defense capability against Class 1 or 2 UAS, low-flying aircraft, and cruise missiles and can use these assets to protect other forces or locations. This capability is augmented by a defensive electronic attack capability to interfere with enemy UAVs and guided munitions.

Turning to the second secondary research question, the MDTF's capabilities as documented above enable it to control a maritime area and prevent its use by an enemy. This is referred to in other service doctrinal literature as sea denial. It can also perform counterreconnaisance activities in these areas against enemy ships and some types of aircraft. The MDTF has an extremely limited ability to occupy terrain but has a greater ability to meet the doctrinal requirements of retaining or securing terrain by preventing enemies from occupying them or being able to effectively attack them through a combination of long-range fires and defensive capabilities. These long-range fires also allow it to block, canalize, or turn enemy forces from key lines of advance in a maritime environment through an increasing density of fire as enemy ships move closer to the MDTF.

2527 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

These tasks are accomplished by using the MDTF's fires to disrupt or interdict enemy forces while they are moving, and the MDTF has a limited ability to neutralize or suppress enemy fires and other tactical activities. The MDTF can defeat or destroy small ground forces or larger naval forces and has the capability of isolating enemy forces using a combination of electronic warfare and fires to prevent reinforcement or resupply of enemy forces that are forward of or isolated from the main body. This is particularly true in the maritime environment of the Indo-Pacific, where enemy forces may be operating on small islands. Finally, the MDTF's surveillance capabilities allow it to conduct initial reconnaissance of the area where it is deployed and to conduct limited security operations such as a screen or an advance guard by providing early warning of enemy forces or using long range fires to prevent enemy forces from approaching to within range of friendly forces.

For the third secondary research question, the MDTF can shape the operational and strategic environment in the Indo-Pacific by deploying to key terrain in the region where it can control key seaways and littoral areas. This enables the MDTF to provide security for U.S. and partner naval forces as they enter the region and provide intelligence to those forces as they move into positions. In the event that conflict breaks out during this process the MDTF can strike targets within its area of influence in order to delay, disrupt, or possibly defeat enemy attempts to prevent friendly forces from moving into theater. This can be viewed as an extension of the MDTF's doctrinal mission to defeat enemy A2/AD efforts carried out by establishing its own A2/AD space and establishing local fire superiority ahead of friendly forces.

2528 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

While not an exhaustive list, this study examined three locations where the MDTF could be deployed in such a role and the function it would perform in that location. The first of these locations was Ishigaki Island, which would allow the MDTF to influence the region around the disputed Senkaku islands or support operations with the Taiwan Straits. A second possible location off the coast of the Philippines offered the ability to influence the South China Sea by exerting control over the Spratly and Paracel islands as well as the sea routes entering the region. Finally, the MDTF can be positioned within the Malacca Strait or at its western end to delay or deny passage of hostile forces and force them onto a longer route that would add multiple days in comparison to a normal transit. This capability is particularly important in the event of a future conflict with China, as it could serve to isolate a portion of China's naval strength from a contested location and allow the U.S. and partner nations to obtain local superiority.

Based on this analysis the answer to the question of how the MDTF can contribute to the Joint Force in the Indo-Pacific stretches across multiple phases of the Joint Combat Operations Model. The presence of the MDTF with its long-range fires and surveillance capabilities can serve as a deterrent to enemy escalation and assist in maintaining operational access for follow-on forces. In the initial stages of a conflict the MDTF can isolate enemy forces and prevent an adversary such as China from massing forces by delaying or disrupting movement of enemy forces. This places the MDTF in line with joint concepts of flexible deterrent and flexible response operations, combined in a single package that can swiftly shift from one type of operation to another. Integrating the MDTF into the Joint Combat Operation Model requires careful consideration of what this expanded role means in that context.

2529 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Although there is no one-size-fits-all operational model, JP 3-0 provides an example of how a joint combat operation can be described as a group of interrelated actions divided among operation shaping, deter, seize initiative, dominate, stabilize, and enable activities. The figure below depicts one such operation from beginning to end, with each activity scaled based on the amount of emphasis placed on each type of activity.

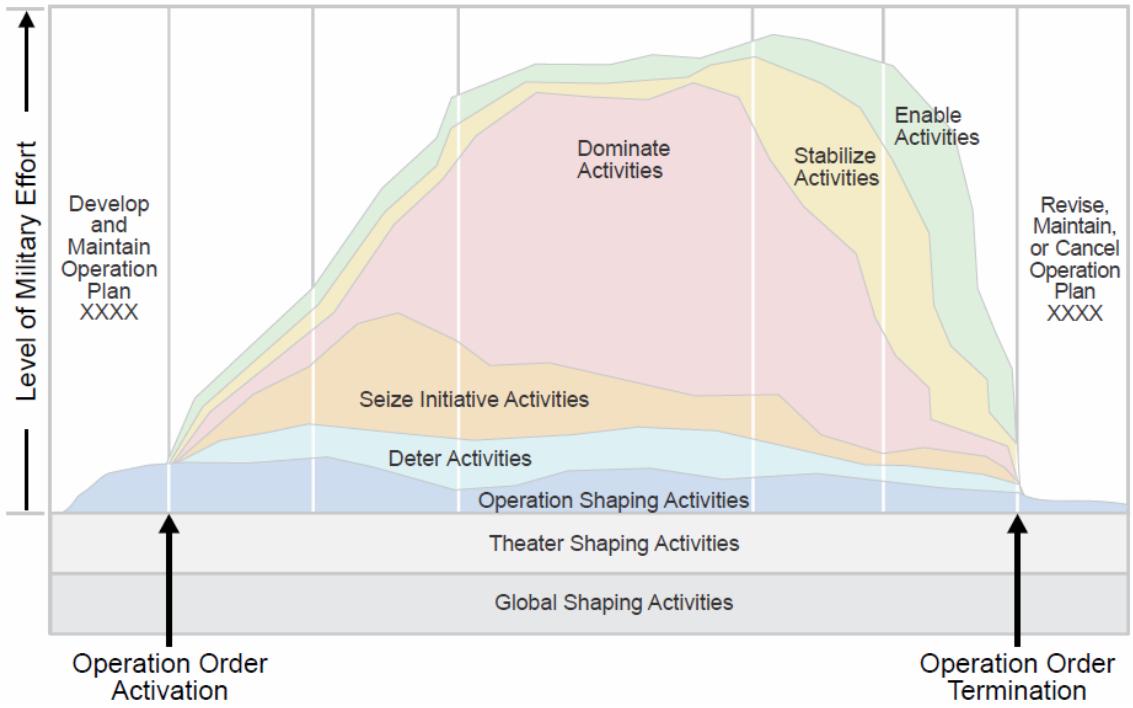

Figure 12. Notional Joint Combat Operation Model

Source: Office of the Chairman of the Joint Chiefs of Staff, Joint Publication 3-0, Change 1, *Joint Operations* (Washington, DC: The Joint Chiefs of Staff, October 2018), V-8.

The figure above depicts a five-phase operation that proceeds from activation of an order to end of mission. The standard use of the MDTF in this figure would most likely occur near the middle of the second phase in support of increases in dominate and

2530 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

seize initiative activities by penetrating enemy A2/AD spaces in support of an opposed entry. The full range of the MDTF's capabilities and application across the range of military operations indicates that it can be used earlier in the operation during the first phase. This provides several benefits supported by the MDTF's ability to swiftly deploy to a strategically significant location as part of a flexible deterrent option.

As the operation continues the MDTF can act in an operational shaping role by isolating enemy forces and conducting long-range strikes as a flexible response option. In a maritime environment it can use fires to restrict access to the site of a crisis and maintain freedom of movement and operational access for follow-on forces. This serves to protect those forces and increase the flexibility of the operational environment as the combat operation shifts into a phase that is more characterized by dominate activities. At this point the MDTF's role transitions to its normal mission of penetrating A2/AD spaces to enable other operations, although the variety of systems that it employs could also be used against other critical targets and facilities that are unrelated to A2/AD missions as part of conducting long-range precision fires.

Recommendations for the Force

In order to fully realize the potential of the MDTF as described in the answer to the primary and secondary research questions above, there are a total of five recommendations that this study makes to the joint force:

1. Exercise and test the MDTF in an A2/AD capacity to validate the concepts outlined in this study. If they are validated, modify the MDTF's purpose and operational concept accordingly and train to this mission.

2531 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. Develop a concept for deploying the MDTF as a flexible deterrence/flexible response option with a pre-developed movement concept. Train and exercise this concept according to the Brigade Support Battalion's requirement to be able to manage a 96-hour rapid deployment. In order to enhance the capability of the MDTF to conduct deterrence in time sensitive situations this should include an initial operating capability that can execute fires with the first turn of cargo aircraft.
3. Equip and train the MDTF in the Indo-Pacific for reconnaissance and security tasks in the maritime domain and other associated domains by ensuring that multi-function electronic warfare (MFEW) capabilities are available for all UAVs in the MDTF. Develop a version of the Sea Guardian package used on the MQ-9B for the MDTF's Gray Eagle or replace a portion of the Gray Eagle platforms with MQ-9B platforms with that package.
4. To mitigate the MDTF's inability to defend against ballistic missiles the MDTF should either have a Patriot battery added to its Air Defense Artillery battalion or be apportioned a Patriot battery in preparation for future operations. This relationship should be formalized, and the MDTF should then conduct training with the identified unit.
5. To enhance the MDTF's ability to control an airspace in a geographically isolated region where Navy or Air Force may not be able to provide air coverage the U.S. military should develop an extended range anti-aircraft capability. This extended range anti-aircraft capability should have a greater

2532 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

range than the Patriot PAC-2 and be designed from its inception to receive terminal guidance from forward sensors.

Possibilities for Future Studies

After 20 years of focusing on counterinsurgency operations the United States Army is going through a conceptual reorganization that can be compared to the changes that took place in the 1980s or the interwar period between World War I and World War II. This includes both doctrinal and technological changes, with the MDTF and similar specialized organizations on the leading edge of this movement. Victory in future conflicts will go to the side that makes the most accurate judgments concerning national and international security interests, national defense strategies, offensive-defensive concepts, and requirements and plans for the future of warfare. Making these judgments requires the development of a body of intellectual work that extrapolates from current trends and our best understanding of developing systems.

One of the strengths of the MDTF is that each doctrinal MDTF is expected to be modified for actual capabilities and missions based on the region it will operate while still retaining the same core concept and requirements regarding force structure capabilities and capacities. This allows for future studies similar to this one to be conducted for other MDTFs that consider the unique requirements of each theater. The second MDTF operating in the European theater has to contend with significantly different terrain but may be able to provide unexpected advantages if placed on key terrain in the Baltic Sea or Mediterranean. An MDTF operating in the Arctic will have different requirements and different force structure considerations as well. This provides a unique opportunity to

2533 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

study those considerations and make recommendations while those units are being designed.

Another possible avenue of study would be examining the MDTF in a multinational construct operating either as part of a multinational joint task force or incorporating similar capabilities from partner nations. The first of these possibilities allows for an expanded appreciation of how the MDTF can operate in concert with other forces as well as how it fits in with a larger military operational concept. A study on similar capabilities existing within partner militaries within a given region could provide a potential framework for using different parts of the MDTF as the core of several task forces to conduct operations in multiple critical locations for an enhanced effect.

The sensitive political climate in the Indo-Pacific means that many nations in the region may be hesitant to directly oppose China also suggests that in some future conflicts a MDTF may be required to operate only from U.S. or Australian territory. Further study in this direction could examine the implications of a MDTF on American Samoa, Guam, or the Northern Mariana Islands. The vast distances of the Pacific Ocean would limit the ability of some components of the MDTF to directly affect China or adjacent waterways but could affect the ability of U.S. forces to access the theater, move within the umbrella of the MDTF, and build combat power in a larger conflict. This placement might also provide an increased role for the MDTF's Long Range Hypersonic Weapon battery.

Finally, a critical assessment of the MDTF's strengths and weaknesses could also be applied against areas where international partners have capabilities that could mitigate those weaknesses. Based on the results of this study, this could include investigating how

2534 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

allies and partners could assist the MDTF with long range air defense systems. Another promising area would include how other forces could assist in providing defense against ballistic missiles. Additional research could include examining the capabilities of other branches of the Department of the Defense in these areas to create templates for joint force packages that could operate as a quick reaction or rapid deployment force while reinforcing the multidomain capabilities of the MDTF.

The outcome of this research and future research into these areas should be published and widely read to influence the development of doctrine, strategies, requirements, technologies, and operational concepts for future use. Serious mistakes in establishing assumptions, threats, and conditions for designing future forces and understanding their potential can be corrected after the fact, but extract a price in blood, time, and resources when those failures come to light during combat. Study and research supporting mission analysis, threat assessment, and measured responses can help to forestall such a cost or provide a starting point for mitigation efforts once future leaders recognize that an error has been made in the past. The purpose of this study and others like it is to ensure that the MDTF and the rest of the Army's Multi-Domain Operations concept realize their full potential when they are called upon to go into battle.

Form Approved
OMB No. 0704-0188

Public reporting burden for the collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204, Arlington VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to a penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.

UA Payload Weight vs. Endurance

DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES. VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

UNCLASSIFIED

UA Sensor Summary

- All UA have an Electro-Optic (EO) and Infrared (IR) capability
- Small UA sensors
  - EO/IR is primary sensor
  - Fixed vs Gimbaled
- Tactical UA sensors (in order of priority)
  - EO/IR
  - SIGINT
  - Radar
  - Comm relay
- Operational & Theater UA sensors (in order of priority)
  - EO/IR
  - Radar
  - SIGINT
  - Comm relay
- Sensor specifications drive UAS costs and capabilities
  - Cost control is critical to development of UAS and UA sensor capabilities

DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING
UNCLASSIFIED

Small UA EO/IR Sensors

- **EO** – Requirement for a facial recognition capability while remaining undetected (NIIRS 8+)
- **IR** – Requirement for identification and tracking while remaining undetected
- **Small UA (SUA)**
  - ***SUA*** are ***expendable*** and ***numerous***
  - Sensors must be
    - Reliable
    - Low Cost
    - Supportable
    - Commercially available
- **Goal for Industry**
  - Gimbaled sensor with EDTV capability (480P)

Raven

System Components:

- 3 Air Vehicles (AV) per system
- 3 Payloads
- One (1) Ground Control Unit
- Remote Video Terminal (RVT)
- Batteries: Mission & Rechargeable
- Carry / Protective Cases
- Battery Charger / Power Supply
- Field Maintenance Kit
- Spares and Repair Parts

Mission:

Army tactical level reconnaissance, surveillance, target acquisition, and battle damage assessment

Capabilities:

- Hand Launched / AutoLand Recovery
- Military P(y)-Code GPS
- AutoNavigation
- Quick Assembly (< 3 min)
- Man Portable / Backpackable
- Quiet
- Reusable (100+ flights)
- Typical Operational Altitude 150-500 ft AGL
- Climb to Operational Altitude in 1-2 mins

Characteristics / Description:

- **Power:** Batteries
  - Mission: Lithium ($LiSO_2$)
  - Rechargeable: Lithium Ion
- **Wing Span:** 4.5 feet
- **Weight:** 4 lbs (w/carrying case, 12 lbs)
- **GCU Weight:** 17 lbs
- **Range:** 8-12 km
- **Endurance (Mins):** 90 (Lithium) / 60 (Lithium Ion)
- **Speed:** 27-60 mph, Cruise 40 mph
- **Payload(s):** High Resolution, Day / Night Camera & Thermal Imager
- **Crew / Manpower:** 2 Soldiers

- Laser Designator Range Finder – Requirement for integration with EO/IR sensor
- Tactical UA (TUA)
  - ***TUA*** are ***attritable,*** fewer in number than SUA
  - Sensors must be
    - Gimbaled turret providing weapons quality precise coordinates
    - Reliable
    - Supportable
    - Commercially available
- Goal for Industry
  - Gimbaled sensor with HDTV capability (720P)
  - Challenge is low cost gimbaled turret
  - Ability to upgrade easily (FPA)

Shadow RQ-7B

Characteristics / Description:

Wing Span	14 feet
Weight	380 lbs
Range	~ 125 km
Airspeed	(60 kt loiter, 105 kt dash)
Altitude	14,000 Ft
Endurance	> 5 Hours @ 50 km
Primary Payload (s)	EO / IR (up to 60 lb)
Launch / Recovery	100m x 50m Area

Capabilities :

- Automatic Landing and Takeoff
- System and Maintenance Section transportable on 3 C-130s
- Early entry capability with 1 C-130
- Compatible with ABCS
- EO / IR Sensor
- TCDL Ready

Unit Composition

- Platoon Set = a System:
  - 22 Soldiers (2 Officers, 20 Enlisted)
  - 4 - Air Vehicles
  - 6 - HMMWVs (Ground Control Station, air vehicle transport, troop transports, maintenance shelter)
  - 3 - Trailers (equipment, launcher)
  - 4 - Remote Video Terminals

Summary

- Cost control is critical to development of UAS and UA sensors
- Standard metadata and standard data formats are:
  - Essential for time sensitive operations
  - Critical component of Global Information Grid integration
- Fusion enhances visual image
- Different sensor capabilities required to combat full range of asymmetrical threats:
  - Small
  - Tactical
  - Operational
  - Theater

14. ABSTRACT
Unmanned aircraft are fulfilling critical roles in Iraq and Afghanistan. They are integral in base defense plans and the protection of key infrastructure. They enable commanders to monitor activity throughout their area of responsibility and direct action, when required. Many policymakers see Unmanned Aircraft Systems as a cost effective alternative to manned aircraft and a way to prevent risking a pilot's life. These systems have a number of advantages over manned aircraft. They are unbound by human limitations. They can remain airborne for long durations, do not require life support systems, do not need to eat or sleep, and they will never say no to a mission. They may minimize friendly loss of life by conducting missions that have a minimal chance of survival. However, unmanned systems also have some disadvantages when compared to manned aircraft. They are still prone to human error due to their being flown by ground-based operators. Their development and procurement cost has grown exponentially as capabilities increase. Current systems are not autonomous and their control is contingent on uninterrupted communications. Their dependence on a constant control signal has contributed to a UAS accident rate 100 times greater than manned aircraft A threat could exploit this need for an uninterrupted data feed by using Electronic Warfare to disrupt this signal, potentially crippling unmanned systems.

ABSTRACT

THE VULNERABILITIES OF UNMANNED AIRCRAFT SYSTEM COMMON DATA LINKS TO ELECTRONIC ATTACK, by Major Jaysen A. Yochim, 118 pages.

Unmanned Aircraft are fulfilling critical roles in Iraq and Afghanistan. They are integral in base defense plans and the protection of key infrastructure. They enable commanders to monitor activity throughout their area of responsibility and direct action, when required. Many policymakers see Unmanned Aircraft Systems as a cost effective alternative to manned aircraft and a way to prevent risking a pilot's life. These systems have a number of advantages over manned aircraft. They are unbound by human limitations. They can remain airborne for long durations, do not require life support systems, do not need to eat or sleep, and they will never say no to a mission. They may minimize friendly loss of life by conducting missions that have a minimal chance of survival. However, unmanned systems also have some disadvantages when compared to manned aircraft. They are still prone to human error due to their being flown by ground-based operators. Their development and procurement cost has grown exponentially as capabilities increase. Current systems are not autonomous and their control is contingent on uninterrupted communications. Their dependence on a constant control signal has contributed to a UAS accident rate 100 times greater than manned aircraft A threat could exploit this need for an uninterrupted data feed by using Electronic Warfare to disrupt this signal, potentially crippling unmanned systems.

ACKNOWLEDGMENTS

This project would have not been possible without the assistance of the staff at the Combined Arms Research Library, Fort Leavenworth, Kansas. These professionals conducted research, coordinated inter-library loans, and obtained copyrights.

I would like to thank my committee, especially Dr. Bill McCollum for all the work he did as my committee chair. He was always supportive of my direction but knew when to intervene to adjust my course. Dr. Bill went above and beyond, from recruiting other committee members, to proof reading volumes of material.

I would like to thank those who contributed interviews to this project. They broke down this highly technical subject into an understandable language. This study would not have been possible without their support.

I must thank my friend, Mariann Foster, who helped edit this study. She never complained about my lack of writing skills and was always supportive. She is a good friend and I do not know what I would have done without her assistance.

My entire career is the responsibility of Mark and Brenda Yochim, my parents. They always believed in my passion for military aviation and my desire to serve. Their daily example of perseverance and fortitude is what has allowed me to succeed.

Finally, I would like to thank my wife Alisa, my daughter Mara, and my son Jansen. This “family break” at Command and General Staff College was busier than I had advertized. Alisa is my anchor and was always there to tell me to suck it up. She never let me feel sorry for myself and lovingly kept me focused on the goal. I am thankful to my kids for their understanding when daddy had to work. My kids give some of the best back scratches.

CHAPTER 1

INTRODUCTION

> We're at a real time of transition, here, in terms of the future of aviation, and the whole issue of what's going to be manned, and what's going to be unmanned, and what's going to be stealth and what isn't. How do we address these threats? . . . . I think we're at the beginning of this change. I mean, there are those that see JSF as the last manned fighter--fighter-bomber--or jet. And I'm one that is inclined to believe that.
>
> — Admiral Michael G. Mullen, USN, Chairman, Joint Chiefs of Staff

Unmanned Aircraft (UA) are fulfilling critical roles in Iraq and Afghanistan. They are integral in base defense plans and the protection of key infrastructure. They enable commanders to monitor activity throughout their area of responsibility and direct action, when required. Many policymakers see Unmanned Aircraft Systems (UAS) as a cost effective alternative to manned aircraft and a way to prevent risking a pilot's life.

These systems have a number of advantages over manned aircraft. They are unbound by human limitations. They can remain airborne for long durations, do not require life support systems, do not need to eat or sleep, and they will never say no to a mission. They may minimize friendly loss of life by conducting missions that have a minimal chance of survival.

However, unmanned systems also have some disadvantages when compared to manned aircraft. UAS are still prone to human error due to their being flown by ground-based operators. Their development and procurement cost has grown exponentially as capabilities increase. Current systems are not autonomous and their control is contingent on uninterrupted communications. Their dependence on a constant control signal has contributed to a UAS accident rate 100 times greater than manned aircraft (Congressional

2610 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Research Service 2005, 2). A threat could exploit this need for an uninterrupted data feed by using Electronic Warfare (EW) to disrupt this signal, potentially crippling unmanned systems.

Military aviation is in a transitional phase. Determining the future force structure and the required equipment is a complex proposition, and this transformation demands extensive research and development. The research and development effort will be expensive and time-consuming. US military aviation stands to remain the dominant global airpower force if their vision of the future force is correct, but if their vision is incorrect, it will be fighting to regain airpower relevancy.

Background

The history of unmanned aerial flight is long and diverse, reaching back to the early years of military aviation. Military aviation, as a distinct organization, was first established in 1912 with the formation of the British Royal Flying Corps (Royal Air Force Organization 2009). Military aviation innovation continued to progress and soon military forces began using aircraft to spot for artillery and limited reconnaissance. The combat effectiveness of aircraft supporting ground warfare resulted in the birth of anti-aircraft artillery, but early anti-aircraft gunners were ineffective, due to inadequate training. In 1917, the British Army requested a system that would improve training for anti-aircraft gunners. The government assigned Archibald Montgomery Low, a pre-war physicist, engineer, and inventor who some consider the father of radio guidance, with the task of developing such a system. On 21 March 1917, he designed and tested the first Unmanned Aerial Vehicle (UAV) known as the Ruston Proctor Aerial Target (Bloom 1958, 142).

2611 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In World War II, the remotely operated aircraft experienced its next evolution. The most famous unmanned systems of World War II were the German V1 and V2 guided munitions. These systems were pre-programmed with an area target, guided by simple autopilots, and were completely autonomous once launched. While impressive and a critical concern for the British, the German Henschel Hs 293 and Ruhrstahl Fritz-X were the most successful unmanned systems of the war. Both were air launched, radio guided, anti-ship bombs and are credited with damaging or destroying 32 allied vessels (Bogart 1976, 62). The German military also used remotely operated Surface-to-Air and Air-to-Air Missiles (AAM) with minimal success. During this period, remotely operated systems were limited by their inability to reliably maintain communication links.

Throughout the Korean and Vietnam War Eras, the use of unmanned target drones, cruise missiles, and reconnaissance drones expanded. However, similar to the German V-1 and V-2, these systems were auto-piloted, and not remotely guided. In 1986, the UAV entered the modern era with the development of the British Phoenix and United States/Israeli Pioneer. For the first time, these systems integrated remote guidance, range, endurance, payload, and cost into a reliable platform. Since 1986, unmanned system design, procurement, and utilization exploded globally (Goebel 2009). Most modern militaries are or have developed UAS programs and numerous countries are producing UASs. Asymmetric threats are also seeking UASs. In 2006, Israel acquired and shot down an Iranian produced UAS operated by Hezbollah, a non-state actor (Eshel 2006).

The use of unmanned systems is becoming a mainstay on the modern battlefield. Unmanned systems gather intelligence, observe key terrain, disable explosives, clear underwater mines, and perform a myriad of other missions. Future plans call for

2612 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

unmanned systems capable of ground combat, medical evacuation, troop transport, logistical support, and innumerable other functions limited only by the human imagination. UAS have become so integrated in modern military operations that some contest that unmanned systems have spurn an emerging Revolution in Military Affairs (RMA) (Edwards 2009, 4). Undeniably, the use of unmanned systems has spread beyond their original design concept.

Military leaders originally intended to utilize remote platforms on dirty, dangerous, and dull missions (Braybrook 2004). The logic was simple; when military leaders determined a mission profile caused undue risk to personnel, unmanned systems provide expendable options. However, the performance of unmanned systems in combat and the information they provide commanders, has transformed the view of these systems. Once a dispensable tool, they are now an invaluable asset. Military forces have become information dependent organizations were command centers serve as the information hub.

The design and layout of Tactical Operations Centers (TOC) support the gathering, processing, and redistribution of information. The geographic center of most TOCs consists of a digital map, a computerized significant event tracker, and a display showing UAS Full Motion Video (FMV). The real-time information provided by these airborne systems is processed and analyzed within the TOC resulting in the development of intelligence. In essence, the UAS has become the commander's window to the battlefield. If required, commanders can rapidly redeploy these systems throughout the battle space ensuring the ability to see the operational environment. While these systems have proven important to combatant commanders, has the United States military become

2613 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

over reliant on UAS? If the answer to this question is yes, then protection of the electromagnetic spectrum must be a mission priority.

Remotely operated UASs require two separate radio communications links to operate: one communications link feeds FMV to a Remote Viewing Terminal (RVT) through a Video Data Link (VDL), the other communication link controls the UAS through a Common Data Link (CDL). The VDL uses an omnidirectional antenna to broadcast its communication feed in all directions, allowing any RVT tuned into the UASs VDL frequency to observe the UASs FMV. Video quality and consistency of reception is dependent on the VDL signal strength. The CDL can use either an omnidirectional antenna or a directional antenna that broadcasts only in the direction of the Ground Control Station (GCS) (Hill 2010).

If a CDL experiences frequency interference, the UA executes a self-recovery program known as a "lost link procedure" and attempts to reacquire the CDL from the GCS. If smaller UA, such as the RQ-11 Raven, fails to reacquire the CDL, it continues its self-recovery program and returns to a preprogrammed recovery point. When some larger UA, such as the RQ-7 Shadow, fail to reacquire the CDL, the operators may identify the UA as rogue and deploy a recovery parachute to avoid endangering manned aircraft (Hill 2010).

The scope of this research is limited to Man-Portable and Tactical UAS as defined in Field Manual (FM) 3-04.15, *Multi-Service Tactics, Techniques, and Procedures for the Tactical Employment of Unmanned Aerial Systems,* dated 3 August 2006. These UAS operate in support of tactical commanders and at altitudes less than 10,000 feet. The systems referenced will primarily be US Army systems. This study presumes design

2614 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

philosophies and technologies are common throughout this class of UAS. However, if systems emerge that demonstrate minimal weaknesses, those systems will be identified as recommendations for future development.

The US military has conducted little research on counter Tactical UAS operations. The UAS field is scientifically complex and this researcher is not a scientist. Rather, the focus of this research is on the operational application of scientifically informed theory. Continuing, this research does not address the science of UAS vulnerabilities. Further scientific research is required to adapt UAS to counter threats once identified.

The primary question of this study is: Are UAS CDLs vulnerable to Electronic Attack (EA)? To address this question, the following secondary questions are relevant:

1. What are the ramifications of an EA on UAS CDL systems?
2. What countermeasures can mitigate EAs?
3. Using DOTMLPF, how has the Army prepared for EW?
4. What UAS are most susceptible to EW?

Significance

Today's commanders are using UASs throughout the battlefield. They have become indispensable to combat commanders and their ability to command and control forces. The Joint force has revised doctrine to account for their abilities to shape the battlefield environment. If threat forces develop a technique to deter UAS operations, it could drastically effect how the US, as well as other militaries, operates. Additionally, the design and procurement of UAS has expanded due to the relative reliability of UAS in an uncontested environment. Consequently, due to budgetary constraints the US military has favored increased funding to the research and development of unmanned systems over

2615 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

manned vehicles. Some military analysts have professed an UA might ultimately replace existing and recently developed observation and attack aviation assets as well as fighter platforms. The aircraft affected would include the OH-58, AH-1, AH-64, A-10, F-16, F-22, and F-35 (Allexperts 2005). Thus, innovative research and development of advanced manned aircraft, specifically attack rotary wing, has been limited in the United States. Instead, the United States has favored modernization of current manned aircraft with minimal planning for replacements. While effective in the current environment, if unmanned systems are susceptible to EA, the future force might not receive the vital services manned aircraft currently provide.

Assumptions

The US military is an expeditionary force that projects its power globally. As such, its equipment tends to be mobile, hardened, and durable. If the equipment requires power, it is often vehicle mounted or tied into a power generation grid. Due to this specialization, US equipment tends to be large and expensive. As an expeditionary force, they tend to fight wars on foreign soil.

Mobility requirements do not bind current or future adversarial forces when planning their internal defenses. Equipment designers do not need to account for mobility or durability in their designs. Their equipment will utilize existing infrastructure and thus have an unlimited power potential. These designs may be technologically advanced, but simple to produce. The simplicity allows for indigenous production. Compiled, these advantages reduce the equipment cost and allow for higher equipment inventories.

Further, an adversary's mission may not depend on shooting down an UAS. As mentioned earlier, commanders utilize the information provided by UAS to plan,

2616 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

synchronize and execute combat operations. They rely upon UASs to increase their situational awareness and expand their command and control (C2) capabilities to assess effects and direct forces as required to achieve mission objectives. But for the adversary, denying commanders the ability to effectively use a UAS may represent a tactical victory.

Throughout history, warfare has driven the adaptation and production of new equipment. Complex equipment, such as aircraft, requires an expensive and lengthy procurement process. The time required to design effective countermeasures is lengthy if an adversary is able to design an effective counter UAS weapon.

Further, historically adversaries have used the US forces Rules of Engagement (ROE) to their advantage. Future adversaries will continue to use the US ROE to their advantage. Their counter-UAS weaponry will be intermixed with their civilian populace. These tactics mitigate the US military's ability to target such weaponry by conventional means.

Definitions of Key Terms

Listed below is a brief glossary of key terms relevant to this study. Based on Joint and Army Publications, these definitions will aid the reader in understanding the concepts and analysis presented in this paper.

Common Data Link (CDL). The means of connecting an UA to a GCS for the purpose of transmitting and receiving flight command data inputs necessary to control UAS while in flight (US Joint Forces Command 2009b, 111).

Countermeasures. That form of military science that, by the employment of devices and/or techniques, has as its objective the impairment of the operational effectiveness of enemy activity (US Joint Forces Command 2009b, 101).

2617 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Electronic Countermeasures (ECM). A subsection of EW, ECMs defend against forms of EA or surveillance including communication jamming, radar acquisition, and radar tracking (US Joint Forces Command 2009b, 101).

Electromagnetic Interference (EMI). Any electromagnetic disturbance that interrupts, obstructs, or otherwise degrades or limits the effective performance of electronics and electrical equipment. It can be induced intentionally, as in some forms of EW, or unintentionally, as a result of spurious emissions and responses, intermodulation products, and the like (US Joint Forces Command 2009b, 135).

Electromagnetic Jamming. The deliberate radiation, reradiation, or reflection of electromagnetic energy for the purpose of preventing or reducing an enemy's effective use of the electromagnetic spectrum, and with the intent of degrading or neutralizing the enemy's combat capability (US Joint Forces Command 2009b, 135).

Electromagnetic Spectrum. The range of frequencies of electromagnetic radiation from zero to infinity. It is divided into 26 alphabetically designated bands (US Joint Forces Command 2009b, 47).

Electronic Attack (EA). Division of EW involving the use of electromagnetic energy, directed energy, or antiradiation weapons to attack personnel, facilities, or equipment with the intent of degrading, neutralizing, or destroying enemy combat capability and is considered a form of fires (US Joint Forces Command 2009b, 47).

Electronic Warfare (EW). Military action involving the use of electromagnetic and directed energy to control the electromagnetic spectrum or to attack the enemy. EW consists of three divisions: EA, Electronic Protection (EP), and Electronic Warfare Support (EWS) (US Joint Forces Command 2009b, 137).

2618 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Line of Sight (LOS). The unobstructed path from a soldier, weapon, weapon sight, electronic-sending and -receiving antennas, or piece of reconnaissance equipment to another point (Headquarters, Department of the Army 2004, 125).

Man-portable UAS. These UAS are small, self-contained, and portable. They usually operate below the coordinating altitude. Their use supports the small ground combat teams/elements in the field. They are self-contained and controlled at the combat team level. Data is usually direct FMV constrained to LOS to the operator only (Headquarters, Department of the Army 2006a, 14).

Remote Video Terminal (RVT). An RVT enables a user to receive UAS video away from a GCS. RVTs are designed to be portable and compatible for operations in battlefield command vehicles and some aircraft (Headquarters, Department of the Army 2006a, 18).

Tactical UAS. Tactical UAS are larger systems that support maneuver commanders at various tactical levels of command and can also support the small combat teams when so employed. They are deployable among the tactical command levels and are operated by specialized UAS units, locally controlled and operated. Data products can expand beyond FMV depending on UAS payload configuration and can be disseminated to combat teams in real time using an RVT (Headquarters, Department of the Army 2006a, 14).

Theater UAS. Theater UAS are generally deployed to support theater-wide requirements. Theater UAS permit varied support to combat team and subordinate tactical command levels depending on the type of UAS. The theater UAS design and robust C2 architecture permit split site operations. Specifically, the UA can be deployed

2619 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to theater with mission C2 and data collection, processing and dissemination being conducted locally or outside of theater of operations under reachback conduits (Headquarters, Department of the Army 2006a, 15).

Unmanned Aerial Vehicle (UAV). A powered, aerial vehicle that does not carry a human operator, uses aerodynamic forces to provide vehicle lift, can fly autonomously or be piloted remotely, can be expendable or recoverable, and can carry a lethal or nonlethal payload. Ballistic or semiballistic vehicles, cruise missiles, and artillery projectiles are not considered unmanned aerial vehicles (US Joint Forces Command 2009b, 419).

Unmanned Aircraft (UA). An aircraft or balloon that does not carry a human operator and is capable of flight under remote control or autonomous programming (US Joint Forces Command 2009b, 419).

Unmanned Aircraft System (UAS). That system whose components include the necessary equipment, network, and personnel to control an unmanned aircraft (US Joint Forces Command 2009b, 419).

Video Data Link (VDL). The means of connecting an UA to a RVT for the purpose of transmitting and receiving FMV (US Joint Forces Command 2009b, 111).

Limitations

This study is limited to the Man-Portable and Tactical UAS classes, the most commonly used systems by tactical units. The US military has conducted limited research on counter UAS operations against these classes and this research is beyond the classification of this study. This study will examine the Army Readiness Center research on UAS reliability but these records are incomplete due to inconsistencies in reporting of Man-Portable UAS accidents. Man-Portable and Tactical UAS are untested in an active

2620 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

EA environment due to the relative age of these technologies. Therefore, no combat findings are available to add to this study. This qualitative study may identify operational theories that require further scientific research. However, it will not present scientifically tested solutions to a known problem, though it may identify an unknown problem that requires a scientific solution. In order to maximize distribution, this study remains unclassified.

Delimitations

The focus of this study is external threats to the UAS CDLs. This study will not cover fully autonomous UAS or their internal navigation control systems. The focus is on UA intended to complete an entire mission sortie through a successful recovery. Therefore, this research does not include remotely guided munitions such as cruise missiles, wire guided missiles, radio guided munitions, or precision guided bombs.

2621 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 2

LITERATURE REVIEW

> Technology is not the limitation . . . it's the ability of people to conceive of ways to use the technology.
>
> — Rich O'Lear, VP for Unmanned Aircraft Systems, Lockheed Martin

Six types of literature are relevant to this study. The first is Joint and service doctrine including Joint Publications (JP), Army FMs, and Multi-Service Manuals that concentrate on the training, operation, and command and control of UAS. Second, government white papers, congressional reports, and service studies contain a vast amount of information. Third, professional journals such as Jane's, Armada International, and Journal of Electronic Defense contain information from analysts, researchers, and manufactures. Fourth, books including institutional textbooks, reference books, and history books detail research and experiences involving UAS. Fifth, to the dynamic nature of this studies subject, this study will review numerous blogs as well as print, video, and web based news reports. Lastly, the UAS industry has published numerous fact sheets, brochures, and information papers to advertise their products.

This chapter will first review the types of literature this study may use to answer the primary research question. Next, this chapter analyzes the existing literature in order to identify the gaps in the record and identify pertinent military trends. Lastly, this chapter describes the significance of the thesis in relation to existing literature.

2622 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Doctrine

Joint Doctrine

The Joint doctrine regarding UAS is not current and does not reflect lessons learned during combat operations in Iraq and Afghanistan. Consequently, Joint Publications (JP) offer little new information regarding UAS training, employment, or command and control. There are also inconsistencies in UAS terminology.

There are four noteworthy Joint or multi-service publications relevant to this UAS discussion. The base JP for UAS is JP 3-55.1, *Joint Tactics, Techniques, and Procedures for Unmanned Aerial Vehicles,* dated 27 August 1993. The focus of this publication is the Reconnaissance, Surveillance, and Target Acquisition (RSTA) capabilities UAS deliver to the battlefield. It attempts to establish basic terminology, determine UAS classifications, identify airspace considerations, and recommend methods of employment. However, most of the Joint doctrine contained in JP 3-55.1 is outdated and does not incorporate lessons learned in Iraq and Afghanistan, or account for UAS innovation over the last decade. This JP does not address employment or considerations of armed UAS. In addition, the publications doctrine uses inconsistent UAS terminology and individual service doctrine terminology often differs from Joint doctrine.

The most current multi-service UAS publication is FM 3-04.15, *Multi-Service Tactics, Techniques, and Procedures for the Tactical Employment of Unmanned Aerial Systems,* dated 3 August 2006. This publication adds fidelity to the tactics, techniques, and procedures introduced in JP 3-55.1. It discusses planning considerations, employment tactics, and communications procedures for armed and RSTA UAS platforms. However, the classification of UAS platforms in FM 3-04.15 differs from the

2623 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

UAS classifications in JP 3-55.1. To establish common terminology, this study uses the UAS platform classifications identified in FM 3-04.15.

The primary procedural control publication for UAS is, JP 3-52 *Doctrine for Joint Airspace Control in the Combat Zone, dated*, 22 July 1995. This literature concentrates on procedural control of UAS in congested airspace to mitigate risk. It discusses considerations requiring attention to integrate UAS into manned airspace, such as difficulties using radar to acquiring and tracking UAS due to their unique design, construction and design profile.

The Joint community's primary Electronic Warfare (EW) doctrine is, JP 3-51 *Joint Doctrine for Electronic Warfare*, 7 April 2000. This publication does not specifically address UAS employment, considerations, or vulnerabilities. Rather, the focus of JP 3-51 is the fundamentals and principles of EW. The Joint environment breaks EW into EA, EP, and EWS. This study draws on the EA and EP aspects of this publication. This information allows for determining what type of EW can affect UAS CDL and what protection designs are possible.

Army Doctrine

There are four Army Field Manuals (FM), Training Circulars (TC), or Army Regulations (AR) pertinent to this study. The capstone Army publication is, FM 3-04-155, *Army Unmanned Aircraft System Operations*, dated 29 July 2009. FM 3-04-155 informs commanders, staff, and soldiers on the operation and employment of UAS. It is the foundation for the further refinement of tactic, techniques, and procedures. In addition to the traditional ISR considerations, this manual accounts for lessons learned during operations in Iraq and Afghanistan and employment of armed UAS. Due to its recent

2624 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

update, FM 3-04-155 is relevant in the current operational environment and lays out the Army's vision for future UAS operations.

The Army's primary training publication for Tactical UAS is, TC 1-600, *Unmanned Aircraft Systems Commander's Guide and Aircrew Training Manual*, dated 23 August 2007. As with all Aircrew Training Manuals (ATMs), TC 1-600 standardizes aircrew training and determines flight evaluation procedures. It also establishes crewmember qualification, refresher, and mission readiness training standards for Tactical UAS, such as the MQ-5 Hunter and RQ-7 Shadow. Tactical UAS crewmembers are school trained and are Military Occupational Specialty (MOS) qualified. They must maintain a higher standard of training than operators of Man-Portable UAS and complete an annual flight physical similar to rated aviators.

The primary Man-Portable UAS training publication is, TC 1-611, *Small Unmanned Aircraft Systems and Aircrew Training Manual*, dated 2 August 2006. This ATM standardizes operator training for Man-Portable UAS. The guidelines and standards identified in TC 1-611 are not as strenuous as TC 1-600. Man-Portable UAS operators do not receive the same extensive training as Tactical UAS crewmembers and do not have an MOS qualification. This publication focuses on operators being proficient in the integration of their UAS in combined arms operations.

The AR mandating UAS operations is, AR 95-23, *Unmanned Aerial Systems Flight Regulations*, dated 7 August 2006. This regulation covers UAS operations, UA crewmember training, crewmember currency requirements, and flight rules. In contrast to the ATMs, AR 95-23 focuses on procedural control of planning, training, and execution

2625 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to ensure safety of operation. This publication is applicable to all Army UAS classifications.

US Governmental Reports

The US government has published four white papers that discuss UAS operations. The most comprehensive of these papers is, *FY2009–2034 Unmanned Systems Integrated Roadmap*, dated April 2009. This paper details the importance of current UAS in the combat environment and lays out the military's future UAS strategy. This paper targets a wide audience including military leaders, academic institutions, UAS industries, and government officials. The purpose of the roadmap is to explain UAS capabilities in the current operational environment and identify potential combat applications on tomorrow's battlefield. This paper culminates with a projection of future UAS technologies, missions, and implications on the 2034 battlefield.

In contrast, the *Defense Science Board Study on Unmanned Aerial Vehicles and Uninhabited Combat Aerial Vehicles*, dated February 2004, focuses on current operations, not future operations. The report details current UAS tactics and technologies found in Iraq and Afghanistan. Unlike the roadmap, this report is a critical review of the current UAS structure and issues recommendations for improvement. One of the issues identified is UAS CDL communications failures (Defense Science Board 2004, 43).

Next, *Unmanned Aerial Vehicles: Background and Issues for Congress*, dated 21 November 2005, is a comprehensive information paper written for members of congress. This article also explains the advantages UAS present on the modern battlefield. This paper includes the implications of UAS production on the American industrial base, and presents considerations for UAS export and possible implications of UAS proliferation.

2626 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In considering export potential, this paper details various UAS types including obsolete systems no longer found in the US inventory.

Lastly, the *Unmanned Aerial Vehicle Reliability Study*, dated February 2003, examines current Defense Department UAS to determine the risk posed by unmanned aviation to persons and property due to accidents. The DOD commissioned this study under its campaign to influence the FAA to allow UAS utilization in national airspace. This study attempts to identify issues of reliability and recommend solutions to improve reliability. Pertinent to this research, the study details UAS mishaps related to communication interference.

Professional Journals

Three noteworthy journals contribute to this study. The most important of these is *Jane's Unmanned Aerial Vehicles and Targets*, a non-governmental journal, not subject to UAS industry influence. It details UAS produced in the US and those produced globally. Jane's explains UAS technology with greater fidelity than any other publication and identifies foreign states with active UAS industries. It also details states that actively export UAS technology. This journal allows for examination of commonalities found in UAS globally and threats related to forces being able to obtain similar systems and develop UAS countermeasures.

Armada International is monthly publication focused on the defense industry and issues a comprehensive annual report on UAS. This annual report details current and future UAS globally, although it is not as detailed as *Jane's Unmanned Aerial Vehicles and Targets.* However, where Jane's tends to focus only on current military systems,

2627 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Armada examines military and prominent civilian systems still in the developmental phase.

The final publication is the *Journal of Electronic Defense* produced by the Association of Old Crows, a nonprofit international professional organization specializing in EW. This journal reports on trends, industry news, and other developments in the EW field. Concerning this study, the journal's EW coverage includes electronic countermeasures (ECM), airborne EA, and command and control warfare.

Books

Four books provide texture to this study. The first of these books is *Advances in Unmanned Aerial Vehicles,* edited by Kimon P. Valaavanis. The book does not focus on military UAS. Rather, it is a compilation of articles written by civilian researchers across the world. It is written and edited by civilians and allows them to share information. The book gives a detailed history of civilian UAS theory and research, and discusses control fundamentals, aspects of navigation, and application of these principles in current projects. Of greatest interest to this study, *Advances in Unmanned Aerial Vehicles* discusses numerous control designs that could provide direction for military UAS CDLs.

In *Modern Communications Jamming Principles and Techniques,* author Richard Poisel explains the science of disrupting modern communications. Dr. Poisel does not write for a military audience. However, the information provided is applicable to military operations. The book discusses the operational use and vulnerabilities of modern communications systems. It identifies forms of jamming including active, passive, structural, and environmental. The book provides examples of jamming techniques and

2628 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

explains their advantages and disadvantages. It also indentifies principles of anti-jamming technology and tactics.

In contrast, *Fundamentals of Electronic Warfare*, by Sergei Vakin, Lev Shustov, and Robert Dunwell is intended for a military audience. The book is a detailed description of EW in modern warfare, and provides a short history of EW and its application in historical context. *Fundamentals of Electronic Warfare* is both a scientific text, which details the mathematical models of EW and an operational text that explains EW tactics. Further, it explains active and passive jamming of electromagnetic energy. Unlike *Modern Communications Jamming Principles and Techniques*, this text concentrates on EW directed against or produced by aircraft.

The final book, *Wired for War*, by P. W. Singer is not a science-based text. Singer conducted an exhaustive study on the science of UAS, current application of UAS technology, and the potential UAS future. Singer believes there is an ongoing UAS RMA and that the proliferation of robotics has changed the face of warfare. This book also identifies robotics limitations and exposes the myth of computer infallibility. Singer discusses the global proliferation of robotics in military and paramilitary organizations, and contends the global proliferation of robotic systems could undermine America's perceived dominance.

Media

This study intends to use two real time sources of information. The first of these is news coverage from print, video, and web based media. On a regular basis, these outlets detail UAS combat operations. However, these sources do have limitations. They report high profile events such as UAS attacks and UAS crashes yet lack many of the relevant

2629 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

facts surrounding these events. Despite these drawbacks, some of these reports may contribute to the depth of this study.

This study also uses a number of professional blogs. The first blog is the Congressional Unmanned Aerial Vehicle Caucus co-chaired by Rep. Howard "Buck" McKeon and Rep. Alan Mollohan of the US House of Representatives. This caucus' mission is to educate members of Congress and the public on the strategic, tactical, and scientific value of UAVs. Another potential blog for review is UAVforum.org, an online working group that discusses global UAS research and advances. Many of the systems discussed on UAVforum are non-US designs and generally not reported on in US sources.

UAS Industry Releases

This study used fact sheets, brochures, and information papers from UAS manufactures. AeroVironment, Inc. and AAI Corporation produced the most important products due to their share of the UAS market. General Atomics Aeronautical Systems, Inc, Honeywell, and Northrop Grumman information was also reviewed to determine their systems capabilities.

These documents are industry advertizements that tend to espouse capabilites and ignore limitations. This study used these products to develop an understanding of system specifications and capabilites.

Review of Current UAS

To call a UAS a remote control airplane is simplistic. An UAS is a complex integration of various technologies designed to operate in austere environments. They

2630 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

consist of three separate major components an UA, a GCS, and a RVT. Multi-echelon military leaders depend on UAS to increase their situational awareness and enable decision-making. The CDL structure of UAS varies based on the size, mission, and capabilities of the UA.

The differing service components have had their own UAS classifications. To prevent confusion, this research utilize the broad multi-service UAS classification as defined in FM 3-04.15, *Multi-Service Tactics, Techniques, and Procedures for the Tactical Employment of Unmanned Aerial Systems,* dated 3 August 2006 (see table 1). This multi-service manual categorizes UAS into three main classes: Man-Portable, Tactical, and Theater UAS. The employment philosophies of differing classes are similar, but the limitations of some airframes require tactical adaptations. UAS within these classifications have similar CDL structure due to common manufactures, similar operational environments, and DOD mandated interoperability directives.

2631 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 1. UAS Capabilities

	Speed (knots)		Maximum Altitude	Maximum Endurance[1]	Maximum Range
	Cruise	Dash			
Man-portable					
Desert Hawk	50	50	1,000 AGL	1 hr	10 km^2
Dragon Eye	45	45	500 AGL	1 hr	10 km^2
Pointer	45	45	985 AGL	1 hr	5 km^2
Raven	34	60	1,000 AGL	1 hr	10 km^2
Silver Fox	50	50	1,000 AGL	10 hrs	32 km^2
Tactical					
Hunter	70	100	15,000 MSL	8-9 hrs	125 $km^{2\,\&\,4}$
IGNAT	70	120	25,000 MSL	30 hrs	500 nm^2
Pioneer	65	110	15,000 MSL	5 hrs	185 km^2
Scan Eagle	70	70	19,000 MSL	15 hrs	110 km^2
Shadow	70	105	15,000 MSL	5 hrs	50 km^2
Fire Scout	80	125	20,000 MSL	6 hrs	280 km^2
ERMP	70	150	29,000 MSL	36 hrs	1200 km^2
Theater					
Global Hawk	310	340	60,000 MSL	28 hrs	5,400 nm^3
Predator	70	117	26,000 MSL	20 hrs	500 nm^3
Predator B	90	220	45,000 MSL	16 hrs	500 nm^3

[1] Endurance equals total time from takeoff to landing.
[2] Range equals range from GCS.
[3] Range equals total mechanical range of UA.
[4] With retransmission, range equals 200 km.

Man-Portable UAS

Man-Portable UAS are small, self-contained, portable systems often employed at the lowest levels of command. This class of UAS operates at lower altitudes and often shares airspace with manned rotary-wing aircraft. Most tactical organizations that employ these systems have a single operator, selected from within the unit, who has attended a qualification course. Man-Portable UAS operators are required to attend a certification course, but do not receive an Additional Skills Identifier (ASI).

2632 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Current Man-Portable UAS are either hand-launched, bungee launched, or take-off vertically. The operator commands the UAS by maintaining a CDL between the UA and the GCS. The UAS broadcasts its FMV to any RVT within range of the system, which is monitoring the correct VDL. Man-Portable UAS have shorter ranges than other systems due to their dependence on LOS communications and lower operating altitudes (Headquarters, Department of the Army 2006a, 14).

These UAS use omnidirectional antennas for both their CDL and VDL. In theory, the simplicity of the antenna design improves CDL reliability and maximizes VDL distribution. Additionally, the omnidirectional antenna configuration and interoperability allows any GCS broadcasting the appropriate CDL frequency to command the UA. This flexibility enables multiple operators to command a single UA by transferring command using a CDL "*handshake*", effectively extending the range of a single UAS. However, an incorrectly performed handshake can result in a disruption of the CDL and cause a crash. Man-Portable UAS rarely utilize this function to avoid risk of an accident (Hill 2010).

Current Man-Portable UAS in include the RQ-16 Tarantula Hawk (T-Hawk), RQ-11 Raven, RQ-14 Dragon Eye, Puma AE, and Wasp. The following is a review of the design characteristics of these current UAS designs (Headquarters, Department of the Army 2006a, 21).

RQ-16 Tarantula Hawk

The RQ-16 T-Hawk, produced by Honeywell Aerospace, is the newest Man-Portable UAS in the US Army inventory. The original Army designation for the system was the XM156 Class 1 UAS and was a subsystem of the Army's Future Combat System (FCS) (Department of Defense 2009, 86). The DODs review of the Army's FCS left the

2633 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

T-Hawk's future in doubt, but seeing the systems potential, the Navy adopted the XM156. In January 2008, the Navy surprised many by placing a surprise order for 186 XM156s and re-designated the system as the RQ-16 Tarantula Hawk (Trimble 2008). In Iraq, the Navy led Multi-Service Explosive Ordnance Disposal Group is currently using 20 T-Hawks to combat roadside bombs.

The T-Hawk is gasoline operated, has a range of up to 10 kilometers, and can remain airborne for 50 minutes (see figure 1). The system includes a GCS, a ground support package, and two UAs. The UA takes off vertically, flies to 100 waypoints at up to 46 Miles per Hour (MPH), can establish a stationary hover over a desired location, and communicates on L-band Ultra High Frequency (UHF). The UAS has a gimbaled sensor capable of recording Electro Optical (EO) and Infra-Red (IR) images. The GCS is capable of recording up to 240 minutes of FMV imagery. The T-Hawk is limited to LOS communications and cannot operate in moderate rain, heavy wind, or high temperatures (Honeywell Aerospace 2008).

2634 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

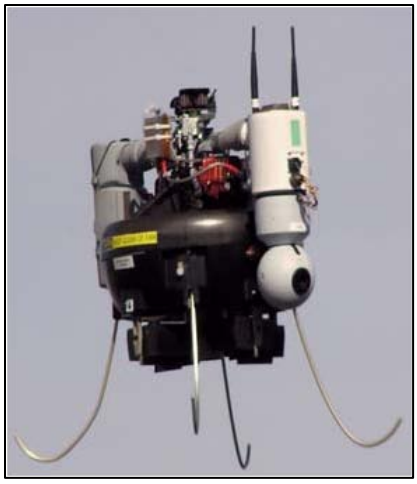

Figure 1. RQ-16 Tarantula Hawk
Source: FY2009–2034 Unmanned Systems Integrated Roadmap, DOD (Photo, FY2009–2034 Unmanned Systems Integrated Roadmap, DOD, 6 April 2009).

RQ-11 Raven

The RQ-11 Raven, produced by AeroVironment, Inc., is the most common Man-Portable UAS in the US military. In 2002, AeroVironment's Flashlight UAS won the Army's small UAV competition and was redesignated the RQ-11 Raven (Net Resources International 2010). The Raven is one of the world's most popular UAS with over 9,000 UAs produced for international clients, including all US military service branches and eight other international partners.

The Raven uses an electrical engine, has a range of up to 10 kilometers, and can remain airborne for up to 110 minutes (AeroVironment Inc. 2009c) (see figure 2). The system includes the Joint Common Interoperable Ground Control Station (JCIGCS), six individual sensor payloads, and three UAs (AeroVironment Inc. 2009e). The RQ-11 is hand-launched, flown either manually or on a preprogrammed route, flies up to 50MPH at 500 feet AGL, and performs a conventional belly landing. The Raven UAS has two

2635 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

sensor payloads; a dual forward and side-look EO nose camera with a stabilized electronic pan-tilt-zoom feature for daytime operations, and a forward and side-look IR nose camera for night operations. The JCIGCS is an AeroVironment designed interoperable GCS that provides FMV, captures screen images, stores data for playback during target assessment, communicates on L-band UHF frequencies, and is compatible with all other AeroVironment UAS. The Raven is limited to LOS communications and cannot operate in moderate rain or high winds (AeroVironment Inc. 2009c).

Figure 2. RQ-11 Raven
Source: Courtesy AeroVironment, Inc., Media Gallary, www.avinc.com (accessed 10 January 2010).

RQ-14 Dragon Eye/Swift

The RQ-14 Dragon Eye is an original Naval Research Laboratory (NRL) project, but AeroVironment designed the latest version of the UAS (AeroVironment Inc. 2009a). Production has been limited with the Navy, Marines, and Special Operations Command

2636 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

(SOCOM) being the primary users. The RQ-14s production run is complete with approximately 630 systems produced (Department of Defense 2009, 84). The RQ-14 is being phased out and replaced by the RQ-11 Raven.

The RQ-14 is a dual engine UAS, which uses electric engines (see figure 3). The system has a range of up to 10 kilometers and can remain airborne for up to 60 minutes. The RQ-14s UA is bungee launched, flown using an autopilot or on a preprogrammed Global Positioning Satellite (GPS) route, flies up to 40MPH at 500 feet AGL, and performs a conventional belly landing. The RQ-14 uses an EO payload for daytime operations and an IR payload for night operations. The Dragon Eye includes three interchangeable payloads: a GCS, three UAs, and two RVTs (AeroVironment Inc. 2009a). The improved Swift variant includes four interchangeable payloads, an AeroVironment JCIGCS, four UAs, and two RVTs. The JCIGCS provides FMV, captures screen images, stores data for playback during target assessment, and communicates on L-band UHF frequencies. The RQ-14 is limited to LOS communications and cannot operate in moderate rain or high winds (AeroVironment Inc. 2009e).

2637 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 3. RQ-14 Dragon Eye / Swift
Source: Courtesy AeroVironment, Inc., Media Gallary, www.avinc.com (accessed 10 January 2010).

Puma AE

The Puma AE, produced by AeroVironment, is an All Environment (AE) UAS intended for land or maritime operations but is still in the developmental phase (AeroVironment Inc. 2009b). The primary proponent for the Puma AE is SOCOM, but no orders have yet been placed. The Puma AE is comparable to the RQ-11 Raven but the Puma AE is waterproof and can land in water (Department of Defense 2009, 67).

The Puma AE has an electric engine, a range of up to 15 kilometers, and can remain airborne for up to 120 minutes (see figure 4). The Puma AE is hand launched, flown on a pre-programmed GPS route, flies up to 45MPH at 500 feet AGL, and performs a conventional belly landing on land or water. The Puma AE utilizes a gimbaled payload that pans plus or minus 180 degrees, tilts plus 10 to minus 90 degrees, uses both an EO and IR sensor, and contains an IR illuminator. The Puma AE uses the AeroVironment JCIGCS, which provides FMV, captures screen images, stores data for

2638 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

playback during target assessment, and communicates on L-band UHF frequencies (AeroVironment Inc. 2009e).

Figure 4. Puma
Source: Courtesy AeroVironment, Inc., Media Gallary, www.avinc.com (accessed 10 January 2010).

WASP III

The WASP III, produced by AeroVironment, is the smallest UAS in the US inventory. Its primary users are the Air Force, Navy, and Marine Corps (AeroVironment Inc. 2009d). The WASP III is a Micro-UAV but the DOD has not established a separate classification for micro systems. The DOD procurement plan does not detail the systems anticipated end strength, but AeroVironment has completed hundreds of systems with production continuing until 2012 (Department of Defense 2009, 68).

2639 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The WASP III uses an ultra-quiet electrically powered engine, has a range of up to 5 kilometers, and can remain airborne for up to 45 minutes (see figure 5). The WASP III is hand launched, flown manually or on a preprogrammed route, flies up to 40MPH at 1000 feet AGL, and performs a conventional belly landing. Three payloads are available for the WASP III: a forward and side-look EO camera, a high-resolution EO camera with electronic pan/tilt/zoom, and an IR imager. It uses the AeroVironment JCIGCS, which provides FMV, captures screen images, stores data for playback during target assessment, and communicates on L-band UHF frequencies (AeroVironment Inc. 2009e). The WASP III is limited to LOS communications and cannot operate in moderate rain or high winds. AeroVironment is also upgrading the WASP III and in the near future plans to offer a waterproof version (AeroVironment Inc. 2009d).

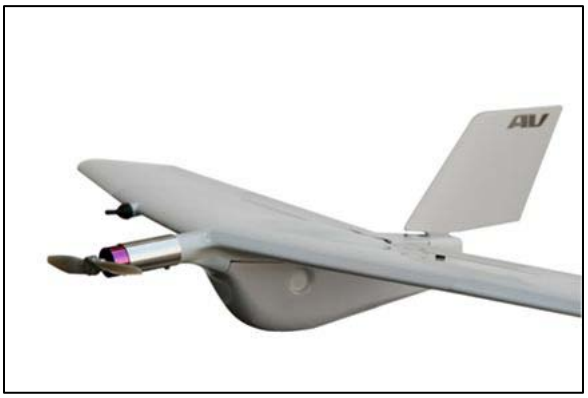

Figure 5. Wasp

2640 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Other Man-Portable UAS

This review of Man-Portable UAS is not exhaustive but represents a cross section of the current US military fleet. The Silver Fox UAS is another UAS program of record produced by BAE Systems. This study did not review the Silver Fox due to its low production, lack of a procurement plan, and limited DOD interest in future development. The Desert Hawk III is a Lockheed Martin design and is primarily used by the Air Force and allied military forces. This study did not review the Desert Hawk III due to limited US procurement. Other UAS may be in the design phase of procurement but due to lack of information, these systems are included in this review (Department of Defense 2009).

Tactical UAS

Tactical UAS are larger than Man-Portable UAS and operates in support of maneuver commanders. These systems operate under restrictions similar to manned aircraft and require a more robust support structure than Man-Portable UAS. Tactical UAS belong to ground brigades, but Combat Aviation Brigades (CAB) often provide oversight as aviation safety experts (Hill 2010). CABs have a limited number of Tactical UAS but plans call for an expansion in CAB systems (Ford 2010). Brigades C2 these systems but they can operate in support of any organization with access to a RVT.

Tactical UASs may be launched using external power, such as a pneumatic catapult, or take off under its own power. In the US inventory, UASs in this class all land by conventional means, but some foreign made Tactical UAS land by parachute (Armada International 2009). These systems require extensive training to operate and pilots must maintain standards similar to rated-aviators. Tactical UAS require high-power mobile GCS to maintain control and are often dependant on maintaining constant LOS

2641 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

communications. These systems have more sophisticated sensors than Man-Portable UAS and use a single sensor payload for all mission profiles. The current fleet of Tactical UAS includes the RQ-7 Shadow, RQ-5 Hunter, I-GNAT, and MQ-1C Sky Warrior/Gray Eagle (Headquarters, Department of the Army 2006a, 21).

RQ-7 Shadow 200

The RQ-7 Shadow, produced by AAI Corporation, is the most common Tactical UAS in the US inventory and is in use by both the Army and Marine Corps (Department of Defense 2009, 89). The RQ-7 Shadow 200 is the flagship airframe of AAI's Shadow family of UAS. The Shadow family includes the Shadow 400 and Shadow 600 (AAI Corporation 2009a). These other Shadow UAS are larger than the RQ-7 and the US military has not shown interest in them. The US Army currently has 63 RQ-7 UAS in its inventory and procurement plans call for 115 systems in total (Department of Defense 2009, 89). In 2006, the Marine Corps selected the RQ-7 as a replacement for the aging RQ-2 Pioneer UAS, but the Marines have not determined their final system strength (Department of Defense 2009, 89).

The RQ-7B uses an Aviation Gas (AVGAS) fueled pusher prop engine, has a range of up to 125 kilometers, and can remain airborne for up to 6 hours (see figure 6). The Shadow 200 is launched using a trailer mounted pneumatic catapult rail system, flown manually, flies up to 140MPH at 14,000 feet MSL, and uses an automated Take Off and Landing System (TALS) to land conventionally on fixed landing gear (Department of Defense 2009, 89). The RQ-7B is equipped with plug-in optical payload (POP) 300, an Israeli made payload that includes a thermal imager, an EO sensor, a laser range finder (LRF), and an IR illumination for target identification (Tamam Division

2642 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2010). The Shadow 200 uses the Army One System Ground Control Station (OSGCS) which can simultaneously operate numerous UA. This is housed in a climate-controlled shelter, provides UA health and fault monitoring, conducts video coding and decoding, and can archive up to 30 days of ISR data (AAI Corporation 2009b). The Shadow is limited to LOS communications and operates using S-band UHF/SHF frequencies for its CDL and C-band SHF frequencies for its VDL (Hill 2010). The Shadow 200 cannot operate in moderate-rain, extreme-winds, or turbulence (AAI Corporation 2009a).

Figure 6. RQ-7 Shadow 200
Source: FY2009–2034 Unmanned Systems Integrated Roadmap, DOD (Photo, FY2009–2034 Unmanned Systems Integrated Roadmap, DOD, 6 April 2009).

MQ-5 Hunter

The MQ-5 Hunter, produced by Northrop Grumman Corporation, is the latest variant of the RQ-5 medium-range Tactical UAS first introduced in 1996 (Department of Defense 2009, 79). The Army is only user of the Hunter and its service life is yet to be determined. The Army has cancelled and recalled the Hunter on numerous occasions out

2643 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of operational necessity. The Hunter's first operational deployment was in support of NATO operations in the Balkans and it is currently operating in Afghanistan and Iraq (Department of Defense 2009, 79).

The MQ-5 operates using a heavy fuel engine, which incorporates a conventional and pusher prop in combination (see figure 7). The Hunter has a range of up to 200 kilometers, can remain airborne for up to 18 hours, and flies up to 125MPH at altitudes up to 18,000 feet MSL. The Hunter takes off conventionally, is manually flown, and lands using fixed landing gear (Department of Defense 2009, 79). The MQ-8 is equipped with an advanced payload that includes an EO/IR sensor, an IR illuminator, a laser range finder designator (LRFD), and a communications relay package (CRP). The MQ-5 can use the GBU-44/B, Viper Strike, a glide bomb that uses the Hunter's LRFD to attack targets. The Hunter uses the same OSGCS as the Shadow 200 allowing for simultaneous operation of numerous UA, is housed in a climate-controlled shelter, provides UA health and fault monitoring, conducts video coding and decoding, and can archive up to 30 days of ISR data (AAI Corporation 2009b). The Hunter is limited to LOS communications and uses a C-band SHF frequency for both its CDL and VDL (Northrop Grumman 2010).

2644 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 7. MQ-5 Hunter
Source: FY2009–2034 Unmanned Systems Integrated Roadmap, DOD (Photo, FY2009–2034 Unmanned Systems Integrated Roadmap, DOD, 6 April 2009).

I-GNAT

The I-GNAT, produced by General Atomics Aeronautical Systems, is an improved version of the GNAT 750 first introduced in 1989 (Department of Defense 2009, 75). The Army procured the I-GNAT in response to a congressional request for additional UAS to support operations in Afghanistan and Iraq. General Atomics Aeronautical Systems produced 25 I-GNATs in numerous variants, but its production run is complete. I-GNATs support operations until their service life expires. The MQ-1C is replacing these systems (Department of Defense 2009, 75).

Depending on the variant, the I-GNAT operates using either an AVGAS or a heavy fuel pusher prop engine with a LOS range of up to 250 kilometers or a BLOS range of 2500 kilometers, can remain airborne for up to 40 hours, and flies up to 140MPH at altitudes up to 25,000 feet MSL (see figure 8). The I-GNAT takes off conventionally, is manually flown, and lands using retractable landing gear. The system is equipped with an advanced payload that includes an EO/IR sensor, a LRFD, and a CRP

2645 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

(General Atomics Aeronautical Systems 2009b). The I-GNAT uses the OSGCS allowing for simultaneous operation of numerous UA, is housed in a climate-controlled shelter, provides UA health and fault monitoring, conducts video coding and decoding, and can archive up to 30 days of ISR data (AAI Corporation 2009b). Most of the I-GNAT variants are limited to LOS communications operating on C-band SHF frequencies. However, some I-GNATs are equipped to use a BLOS satellite communications (SATCOM) radio operating on Ku-band EHF frequencies (General Atomics Aeronautical Systems 2009b).

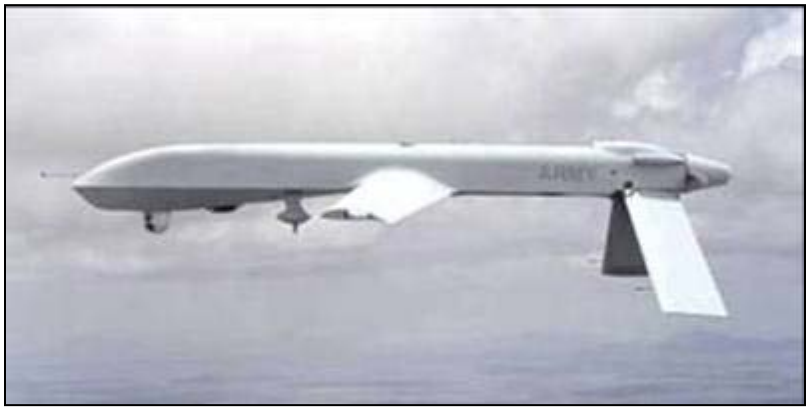

Figure 8. I-GNAT
Source: FY2009–2034 Unmanned Systems Integrated Roadmap, DOD (Photo, FY2009–2034 Unmanned Systems Integrated Roadmap, DOD, 6 April 2009).

MQ-1C Sky Warrior/Gray Eagle

The MQ-1C Gray Eagle, produced by General Atomics Aeronautical Systems, is an upgrade of the MQ-1 armed Predator UAS produced specifically for the Army. The MQ-1C is the end product of the Army's Extended Range/Multi-Purpose (ERMP)

2646 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

development program. It was original designation was the Sky Warrior, but the Army has recently re-designated the UAS as the Gray Eagle (Jensen 2010). Production of the MQ-1C is ongoing and systems are operating in Iraq and Afghanistan in support of the War on Terror. The Army plans to procure 11 complete systems with a total production of 132 airframes (Department of Defense 2009, 78).

The MQ-1C operates using a heavy fuel pusher prop engine with a LOS range of up to 500 kilometers or a BLOS range of up to 1200 kilometers, can remain airborne for over 30 hours, and flies up to 170MPH at altitudes up to 29,000 feet MSL (General Atomics Aeronautical Systems 2009a) (see figure 9). The MQ-1C takes off conventionally, is manually flown, and lands using retractable landing gear. The system is equipped with a payload that includes an EO/IR sensor, a Synthetic Aperture Radar/Ground Moving Target Indication (SAR/GMTI) sensor, a LRFD, and a CRP. The MQ-1C can use up to four laser guided AGM-114, Hellfire missiles, which use the systems LRFD to attack targets. The MQ-1C uses the OSGCS allowing for simultaneous operate numerous UA, is housed in a climate-controlled shelter, provides UA health and fault monitoring, conducts video coding and decoding, and can archive up to 30 days of ISR data (AAI Corporation 2009b). The Gray Eagle is capable of either LOS or BLOS communications using Ku-band EHF frequencies (General Atomics Aeronautical Systems 2009a).

Analysis of Literature

Current doctrine focuses on the employment of UAS. The doctrine does address considerations when operating an UAS in vicinity of other friendly activity and cites concerns with UAS control in vicinity of Counter-Improvised Explosive Device (C-IED) jammers. The doctrine recommends avoiding flight within a set distance of active jammers, turning jammers off when using UAS, or programming jammers to not broadcast against the UAS designated frequency. The doctrine also states that operation of multiple UAS in a concentrated area could cause CDL interference.

The government reports recognize the occurrence of CDL communication jamming. One report claims that 11 percent of UAS accidents are a result of

2648 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

communications failures (Office of the Secretary of Defense 2003, 53). Unlike the doctrine that identifies the likely sources, government reports do not reference possible sources of signal interference. The reports recommend technological development to mitigate CDL interference.

Only one book, *Wired for War*, by P. W. Singer, directly addresses incidents of military UAS CDL interference. In addition, this book identifies sources of natural interference not addressed in any of the governmental publications. Like other military tactics, EW is a continuously adapting field of countermeasures. The books do offer civilian applications, which could be altered for military UAS operations.

Gaps in the Record

Doctrine openly acknowledges that US equipment can interfere with UAS data links. CDL communications appear to be susceptible to both jamming and mimicking. The government reports identify improvements required in CDL technology. The books suggest that any radio frequency can be jammed.

There is limited literature addressing enemy counter-UAS attacks. However, doctrine does acknowledge the possibility that enemy forces may attack UAS. It does not identify possible vulnerabilities the enemy may exploit, nor does it provide recommendations to counter an enemy attack against UAS.

Trends

The ongoing trend in the military is to increase and expand unmanned operations. Most of the government publications stress the integration of UAS throughout the operational environment and detail the advantages UAS provide to the combat leader.

2649 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Generally, current doctrine focuses solely on UAS employment. The military has not acknowledged or addressed contingencies when operating in a non-permissive UAS environment. The most troubling trend is a sense of ignorance regarding UAS limitations.

Significance of Thesis in Relation to Existing Literature

Existing literature focuses on the advantages of UAS employment. In comparison, this study focuses on vulnerabilities in a non-permissive UAS environment. Literature has identified the CDLs susceptibility to communications failure. However, these failures are attributed to specific scenarios involving operations in the vicinity of C-IED jammers or multiple UAS. Civilian literature attests such failures could occur from numerous manmade or natural sources. Therefore, to determine these vulnerabilities, this study will identify occurrences of UAS failure during training and execution of combat operations.

As seen in this review, these six types of literature provide a comprehensive view of UAS CDL and possible vulnerabilities to these control structures. The Joint doctrine establishes some common terminology between services but is limited by the age of the documents. Army doctrine is tactically based and draws on lessons learned during combat operations. It details considerations for the employment of UAS in the operational environment. Books explain the science of UAS communications and the possibility of interference with UAS data links. Professional journals provide information by subject matter experts (SME) in the field of UAS, communications, and EW. Finally, media sources are the most dynamic literature and provide near real time information on current UAS operations. This review has also identified gaps in the record and trends in existing literature.

CHAPTER 3

RESEARCH METHODOLOGY

> Discovery is to see what everybody else has seen, and to think what nobody else has thought.
>
> — Albert von Szent-Gyorgyi

While some literature is available on UAS CDLs, the current information does not provide sufficient detail to identify the scope of the problem. To answer the research questions presented in chapter 1, this qualitative study of UAS CDL structures analyzes the current record and conducts interviews to add to the record. In order to achieve a comprehensive answer, this process includes an evaluation of current and developmental military and civilian UAS CDLs. This study will propose recommendations to change military UAS planning to account for operations in a non-permissive UAS environment.

This chapter explains the steps taken previously to gather available information. This study identifies information that necessitates interviews with experts and those with experience in the field pertaining to this study. Lastly, this chapter describes the research methodology and the advantages and disadvantages to the methodology.

Information Gathering

To identify relevant doctrine, regulations, and unclassified publications, this study extensively reviewed Joint, Army, Navy, Marine, and Air Force electronic publications. Due to the dynamic nature of UAS technology, numerous web-based resources have been reviewed, including Association for Unmanned Aircraft Systems International, Congressional Unmanned Aerial Vehicle Caucus, The Association of Old Crows, Space Media Network, and the Air Force Research Institute. The US Army Combined Arms

2651 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Research Library in Fort Leavenworth, Kansas, provided access to UAS development and procurement plans. Combined Arms Research Library research librarians provided government reports, journals, and other relevant literature.

Interview Selection

Limited information is available in current literature regarding vulnerabilities to UAS CDLs. Consequently, this study necessitated conducting interviews to gather relevant institutional knowledge. Either the military or the civilian UAS community may help answer the research question. This study interviews experts from both communities in order to conduct a comprehensive study. Additionally, numerous variables have been identified that could affect the results of this study. The interviews must address these variables to minimize information gaps relevant to the primary question.

The initial interviews were conducted with experts in UAS development. The US Army UAS Project Managers at Redstone Arsenal, Huntsville, Alabama were the primary target of these interviews. These project managers are experts on the operational design of current and future Army UAS. These interviews were intended to identify known limitations to UAS CDLs and the Army's attempts to mitigate these risks in current and future UAS.

This study also interviewed civilian UAS engineers and designers currently conducting research and development. The purpose of this interview was to compare and contrast the differing design characteristics. This study determines if civilian and military designs suffer from similar limitations. Where design differences exist, what civilian applications have potential military applications?

2652 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In addition, this study interviewed Observer/Controllers (OCs) from the National Training Center (NTC), Fort Irwin, California, to determine the frequency of UAS CDL failures in a permissive peacetime environment. This was intended to help determine how often CDL interference occurs and what systems are most vulnerable. However, not all incidents of UAS CDL interference amount to an accident that requires an official accident investigation. Due to this, the official accident statistics may only account for UAS accidents requiring an investigation, thus limiting the validity of accident data.

Lastly, this study interviewed experts in the EW community. These experts assist in understanding the science of EW. Understanding the science of EW helps determine if UAS CDLs are vulnerable to UAS attacks. Additionally, if the study finds that UAS CDLs are susceptible to EW attacks, the EW expert may recommend changes to improve UAS communications security.

These interviews were conducted using 20 base questions and additional secondary interview questions determined during the course of the interview. Interview participants provided answers based on individual knowledge when possible. Some interviewees were not capable of answering certain questions. A digital recorder was used to capture information and ensure obtained data is not lost. The basic interview questions were:

1. On what radio bands do UAS CDL and VDL communicate? Please explain communication bands used for current and future Man-Portable and Tactical UAS.

2. Do current UAS CDLs experience interference? What conditions contribute to possible interference?

3. Are certain UAS or classes of UAS more likely to experience interference?

2653 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

4. What is shadow jamming or self-jamming? How common is this phenomenon?

5. FM 3-04.15, *Multi-Service Tactics, Techniques, and Procedures for the Tactical Employment of Unmanned Aerial Systems*, dated 3 August 2006, states, "Users must be aware of enemy actions and environmental factors that can limit the effectiveness of UAS communications." What enemy actions or environmental conditions affect UAS communications?

6. How often do incidents of UAS CDL interference occur in Iraq or Afghanistan?

7. Do C-IED systems employed in Iraq and Afghanistan interfere with UAS CDLs? What classes of UAS are more susceptible to C-IED interference?

8. Are beyond line of sight (BLOS) communications more or less likely to encounter interference?

9. What are the lost link procedures for current and future UAS?

10. How can commanders or UAS operators mitigate CDL interference risks?

11. The *Unmanned Aerial Vehicles: Background and Issues for Congress*, dated 21 November 2005, reported that UAS have 100 times greater accident rate than manned aircraft. Is this still a valid statistic or has UAS reliability improved?

12. On 17 December 2009, *The Wall Street Journal*, reported that insurgents had compromised UAS VDL communications. Have insurgents successfully compromised UAS CDL communications?

13. On 31 December 2008, *CBS News*, reported that Palestinian militants issued an open request on an extremist blog seeking assistance in developing technology with the capability to "detect, intercept and jam UAV signals". Have similar additional threats been issued? Does such requests factor into UAS design considerations?

2654 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

14. Do current UAS possess adequate electronic countermeasure (ECM) protection? What ECM modifications will current UAS receive?

15. What size issues must Program Executive Office Aviation (PEO AVN) consider when developing ECM devices? What size concerns are most difficult to overcome?

16. What redundancy is built into current UAS CDLs? What redundancy is being designed into future UAS CDLs?

17. Do current UAS Doctrine, Organization, Training, Material, Leadership, Personnel, and Facilities (DOTMLPF) accurately account for UAS shortcomings or vulnerabilities? What adjustments are required in the UAS DOTMLPF to account for UAS shortcomings or vulnerabilities?

18. Does PEO AVN research civilian UAS CDLs for possible military applications?

19. Does PEO AVN participate in the Navy's annual Black Dart counter-UAS exercise at Naval Air Weapons Station, China Lake? Should PEO AVN participate in this exercise?

20. What additional publications can advance this study?

Research Methodology

This study used the DOTMLPF construct to address the primary and secondary questions posed in chapter 1. It focused mainly on the adequacy of Joint and Army doctrine to prepare for EW, structure of UAS organizations to provide oversight of EW preparations, the training operators receive to identify EW, and materials that affect a

2655 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CDLs ability to cope with interference. This use of the doctrine, organization, training, and material portions of DOTMLPF will continue throughout chapters 4 and 5.

Advantages and Disadvantages of Methodology

The advantage to this methodology is the inclusion of interviews with the US Army's experts in UAS design and EW fields. This technique directly addressed the gaps identified during the literature review. Additionally, including the civilian UAS community brought a fresh perspective and potential alterations to military UAS designs.

The disadvantage to this methodology is that identified issues may not have near term solutions. It may not be possible to incorporate ECM on some UAS classifications due to size and weight limitations. The field of EW research and development is also very dynamic and ECM devices effectiveness may be short lived. While this study may find that UAS CDLs are vulnerable, those vulnerabilities may be acceptable due to a number of other considerations.

As seen in this chapter, this study relied heavily upon interviews to address gaps identified in the available record. Interviews with both military and civilian UAS researchers allowed the researcher to compare and contrast differing design philosophies. This study used interviews, doctrine, and government reports to recommend changes to the UAS DOTMLPF construct. Experts across the UAS spectrum were interviewed to ensure this study is comprehensive. However, technological limitations may not allow an adequate recommendation for all UAS classifications.

2656 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 4

ANALYSIS

> I am concerned about the continued decline in research-and-development funding. From 1980 through today, our investment in basic defense research as a percentage of gross domestic product has declined by 50 percent. . . . choosing to win in Iraq and Afghanistan should not mean our country must also choose to assume additional risk. . . . Who is thinking about the war in 2015? Or the war in 2030?
>
> — Rep. Howard "Buck" McKeon, US House of Representatives

This chapter focuses on the doctrine, organization, training, and material portions of the DOTMLPF construct. This study analyzes the UAs identified as Man-Portable and Tactical UAS in FM 3-04.15, *Multi-Service Tactics, Techniques, and Procedures for the Tactical Employment of Unmanned Aerial Systems,* dated 3 August 2006. First, this chapter defines criteria for Man-Portable UAS classification and reviews the design, capabilities, and employment of the major systems. The study then examines the criteria for Tactical UAS and conducts a similar review of major Tactical UASs. Lastly, the analysis focuses on the doctrine, organization, training, and material considerations that influence UAS CDLs.

Doctrine

Doctrine is composed of the fundamental principles and codified briefs direct action or motive to a common philosophy. Historically, the armed services have struggled to nest their individual service doctrines in a manner that supports mutual operations. To force cooperation, The Chairman of the Joint Chiefs of Staff (CJCS) issues guidance known as Chairman of the Joint Chiefs of Staff Instruction (CJCSI). This directive dictates the procedure for the development of collaborative Joint doctrine. In CJCSI

2657 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

5120.02B, *Joint Doctrine Development System*, dated 4 December 2009, the CJCS charges the Commander, United States Joint Forces Command Commander (CDRUSJFCOM), to oversee Joint doctrine production. This qualitative study examines both Army and Joint doctrine to determine the adequacies of their considerations for UAS operations in an EW threat environment.

This section reviews Army and Joint doctrine to determine planning considerations, recommendations, or mitigations for operating Man-Portable and Tactical UAS in an EW rich environment. The RQ-11 Raven is the primary example of Man-Portable UAS due to its extensive use throughout the Joint forces. The RQ-7 Shadow is the primary example of Tactical UAS due to its use by both the Army and Marines. Findings for these systems are transferable within their classifications due to system commonalities and interoperability.

Joint and Multi-Service

The first mission of Joint operations is to establish a common language, but dissimilar terminology has posed a problem for Joint UAS operations. UAS technology is dynamic and defining language today might not account for systems in development. The services might have differing logic behind their language structure. Some UAS classifications are based by system specifications and capabilities, and some describe the environment in which the system operates. A consistent naming convention allows for universal understanding by system operators and non-operators. Clear classification becomes critical if this study determines certain system criteria, such as their operational environment, increases susceptible to CDL disruption and EA.

2658 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In recent years, UAS have held numerous classifications depending on the source and age of the defining publication. For example, the RQ-11 Raven has held numerous classifications including a Close Range-UAV (CR-UAV), Small-UAS (SUAS), Man-Portable UAS, Tier-1 UAV, Tactical-1 UAS, and Group-1 UAS. This study reviewed various publications including JP-55.1, *Joint Tactics, Techniques, and Procedures for Unmanned Aerial Vehicles,* dated 27 August 1993, FM 3-04.15, DODs UAS strategic planning document, *FY2009–2034 Unmanned Systems Integrated Roadmap,* dated April 2009, and FM 3-04.15, *Multi-Service Tactics, Techniques, and Procedures for the Tactical Employment of Unmanned Aerial Systems,* dated 3 August 2006 to determine classifications.

JP 3-55.1, *Joint Tactics, Techniques, and Procedures for Unmanned Aerial Vehicles,* dated 27 August 1993, is the capstone Joint UAS manual. The validity of this publication in the current operational environment is limited due to its age. The JP 3-55.1 identifies smaller systems, such as the RQ-11 Raven, as CR-UAVs and larger systems, such as the RQ-7 Shadow, as Medium Range-Unmanned Aerial Vehicle (MR-UAV). This classification is not in any other service publication but these are common system descriptions in the civilian UAV community (Blyenburgh 2008, 5)(see table 2). The UAVs capabilities determine the identification, not the environment in which the system operates (US Joint Forces Command 1993, 14).

2659 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 2. Civilian UAS Classes					
Classification	Description	Weight	Range	Altitude	Endurance
Mini-UAV	Miniature	Less than 25 kilograms	Less than 10 kilometers	Less than 500 feet	Less than 2 hours
CR-UAV	Close-Range	25 – 150 kilograms	10-30 kilometers	Less than 10,000 feet	2-4 hours
SR-UAV	Short-Range	50 – 250 kilograms	30-70 kilometers	Less than 10,000 feet	3-6 hours
MR-UAV	Medium-Range	150 – 500 kilograms	70-200 kilometers	Less than 16,500 feet	6-10 hours
MALE	Medium-Altitude Long-Endurance	1000 – 1500 kilograms	Over 500 kilometers	16,500-25,000 feet	24-48 hours
HALE	High-Altitude Long-Endurance	Over 2000 kilograms	Over 2000 kilometers	Less than 65,000 feet	24-48 hours
STRATO-UAV	Stratospheric	Over2500 kilograms	Over 2000 kilometers	Over 65,000 feet	24-48 hours

Source: Created by author using data from *EASA UAS Workshop*, European Aviation Safety Agency, Blyenburgh, 2008.

The *FY2009–2034 Unmanned Systems Integrated Roadmap*, dated April 2009, is the DODs strategic planning guidance for all current and forecasted unmanned systems. The roadmap identifies smaller UAS, such as the RQ-11 Raven, as a Group 1 UAS and larger UAS, such as the RQ-7 Shadow, as a Group 3 UAS. The specifications and performance of the UAS determines its classification, not the UASs operational environment. The group identification is broad and does not account for the growing micro-UAS field (see table 3). Additionally, this group identification is of little value to a non-operator who does not know the specifications and performance parameters of a specific UAS (Department of Defense 2009, 110).

2660 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 3. Joint UAS Groups			
UAS Category	Weight	Altitude	Speed
Group 1	Less than 20 pounds	Less than 1,200 feet AGL	Less than 100 knots
Group 2	21-55 pounds	Less than 3,500 feet AGL	Less than 250 knots
Group 3	Less than 1320 pounds	Less than 18,000 feet AGL	Less than 250 knots
Group 4	Over 1320 pounds	Less than 18,000 feet AGL	Any speed
Group 5	Over 1320 pounds	Over 18,000 feet AGL	Any speed

Source: Created by author using data from *FY2009–2034 Unmanned Systems Integrated Roadmap*, Department of Defense, 2009.

The FM 3-04.15, *Multi-Service Tactics, Techniques, and Procedures for the Tactical Employment of Unmanned Aerial Systems,* dated 3 August 2006, is the most relevant UAS publication with Joint considerations. It identifies smaller UAS, such as the RQ-11 Raven, as a Man-Portable UAS, and larger UAS, such as the RQ-7 Shadow, as a Tactical UAS. The operational environment of the UAS and general system capabilities determine this classification (see table 4). This operational environment class identification means a similar system may fall into multiple categories dependant on utilization. For example, the FM 3-04.15 calls the MQ-1B Predator a Theater UAS and the MQ-1C Sky Warrior a Tactical UAS due to the MQ-1Cs planned employment (Headquarters, Department of the Army 2006a, 21).

2661 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 4. Multi-Service UAS Classifications			
Classification	Size	Altitude	Characteristics
Man-Portable UAS	Small, self-contained	Below coordinating altitude	-controlled at the combat team level. -Data is usually FMV constrained by LOS. -Data may be disseminated to brigade/battalion TOCs. -Imagery processing/interpretation is limited to the combat team.
Tactical UAS	Larger systems with more robust requirements	Above coordinating altitude	-Operated by specialized UAS units. -Products can expand beyond FMV depending on payload. -Imagery processing/interpretation may be conducted by intelligence units. -Communication may be LOS dependant.
Theater UAS	Large systems	Above coordinating altitude	-Operated by specialized UAS units. -Numerous products available depending on payload. -Imagery processing/interpretation may be conducted by local intelligence units or reach back intelligence organizations. -BLOS Communications.

Source: Created by author using data from *Multi-Service Tactics, Techniques, and Procedures for the Tactical Employment of Unmanned Aerial Systems*, Headquarters, Department of the Army, 2006.

UAS terminology is continuing to evolve as new systems are developed and fielded. The current Joint community classification is the group identification associated with the *FY2009–2034 Unmanned Systems Integrated Roadmap*. The roadmap includes five UAS groups separated by gross weight, operating altitude, and airframe speed (Department of Defense 2009, 110). The group system in the roadmap requires knowledge of a specific UAS, but the class system in the FM 3-04.15 requires general knowledge of the UAS (Headquarters, Department of the Army 2006a, 21). This study is using the class system identified in FM 3-04.15, *Multi-Service Tactics, Techniques, and*

2662 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Procedures for the Tactical Employment of Unmanned Aerial Systems, due to its ease of use for a general audience.

This study defines threats to UASs and evaluates doctrinal mitigation of these threats. The focus of research is EW threats directed against Man-Portable and Tactical UAS but minimal information was available due to their limited employment. Information was available for attacks against larger Tactical and Theater UAS but these systems experienced conventional attacks, not EAs. There are three verifiable accounts of attacks against UAS conducting operations and these incidents provide direction for this study.

The first incident occurred in Israel during the 2006 Israel-Hezbollah War in southern Lebanon. On 7 August 2006, an Israeli F-16 shot down an Iranian built Ababil-T UAS using an AAM (Weiss 2006). Israel reported shooting down two additional Iranian UAVs less than a week later, but these claims are in dispute. These attacks each used fighter aircraft employing conventional air superiority tactics.

The next incident occurred in Georgia during the 2008 build up to the South Ossetia War. On 21 April 2008, the Georgian government operated an Israeli built Hermes UAS over their disputed Abkhazian region. The Georgian government accused the Russians of shooting down their aircraft, a claim the Russian government denied. The Georgian government released a video it claims shows a Russian MIG-29 attacking their UAV using an AAM (BBC News 2008).

The last confirmed incident occurred in 2009 during Operation Iraqi Freedom. Coalition forces did not confirm the incident for a month, but coalition forces reportedly tracked the Iranian UAV over Iraq for 70 minutes before shooting it down. A coalition

2663 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

fighter shot down the UAV but the report did not state how the aircraft downed the UAV. The Iranian system was an Ababil-3, similar in size to the MQ-1B Predator (Reid 2009).

These incidents all involved fighter aircraft attacking Theater UAS using conventional air superiority tactics. The value of these attacks in identifying threats to Man-Portable and Tactical UAS is limited. Such tactics could be effective against larger Tactical UAS but would be impractical against Man-Portable UAS. Countering smaller Tactical and Man-Portable UAS requires unconventional methods either not yet produced or not yet released to the public.

In 2008, the effective Israeli airstrikes of Operation Cast Lead resulted in a more realistic and plausible threat against these smaller systems. These airstrikes decimated the Hamas terror network leadership within the Gaza Strip and prompted militants to request external technological support (Ronen 2008). On 31 December 2008, a militant group identified as "The Sons of Palestine" used a jihadist Blog, m3ark forum, to request assistance from "anybody who could suggest a way to detect, intercept and jam the electronic signals transmitted by Israeli reconnaissance UAVs" (CBS News Investigates 2008). This insurgent group had somehow identified the ability to EA UAS but it is unknown how they came to this determination. There is no evidence that this group received the assistance they sought, but this request demonstrates the technological networking capability of asymmetric threats.

This study reviewed the Joint and service publications to identify perceived UAS threats and examine the adequacy of threat mitigation. The focus of this study is threats to UAS CDLs, but this study reviewed all forms of counter-UAS to be comprehensive.

2664 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JP 3-55.1, *Joint Tactics, Techniques, and Procedures for Unmanned Aerial Vehicles*, dated 27 August 1993, the capstone Joint UAS publication is woefully inadequate in its counter-UAS planning guidance. It identifies UAS employment opportunities, but fails to address any threat to UAS operations.

JP 3-30, *Command and Control for Joint Air Operations*, dated 12 January 2010, is the newest JP that addresses UAS operations and does a better job in identifying the potential implications of disrupting CDL communications. It explains that UAS and manned aircraft operate similarly, but that operating UAS requires special considerations. JP 3-30 states, "In the event of lost communications, a manned aircraft will typically press with the mission . . . (UAS) rely on a nearly continuous stream of communications to successfully complete a mission . . . communications security, and specifically bandwidth protection (from both friendly interference and adversary action) is imperative" (US Joint Forces Command 2010, 83). Despite the publication not being a UAS manual, JP 3-30 is the best Joint planning tool for UAS operations.

Lastly, this study reviewed FM 3-04.15, the multi-service publication that fills the void in Joint UAS doctrine. FM 3-04.15 addresses conventional threats to UAS operations once and its mitigation guidance is only applicable to Theater UAS. It states, "Cloud decks may make it desirable to station the UAS in a low-altitude environment, but minimum altitude limitations and/or enemy threat systems may restrict this option. Against an overcast cloud background, the UA may be highlighted, aiding AAM, antiaircraft artillery (AAA), and surface-to-air missile (SAM) threat operators." The counter-UAS threats identified are not practical means for use against Tactical or Man-

2665 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Portable UAS and it makes no mention of EW threats. This guidance is of little value to these lower altitude systems.

US Army

This study took a different approach reviewing Army publications and split its focus into two areas. First, this study examined Army maneuver doctrine to determine the adequacy of employment planning and considerations when integrating UAS into operations. Second, the study examined how well Army doctrine addresses EW threats to UAS operations.

The tactically focused review of maneuver doctrine included FM 3-90.6, *The Brigade Combat Team*, August 2006, FM 3-90.5, *The Combined Arms Battalion*, dated April 2008, FM 3-20.96, *Reconnaissance Squadron,* dated September 2006, and FM 3-21.10, *The Infantry Rifle Company*, dated July 2006. These publications all do an outstanding job integrating UAS in to all aspects of operations including all types of offensive, defensive, security, and reconnaissance operations. However, these manuals do not address threats to UAS operations or contingency planning when operating a non-permissive UAS environment. The only Army publication that addresses limitations to UAS operations is FM 3-20.971, *Reconnaissance and Cavalry Troop*, dated August 2009. FM 3-20.971 identifies issues such as vulnerability to enemy fire, acoustic signature, and LOS communications that may limit UAS operations. Most of these publications discuss EW, but none offer planning considerations for UAS operations on an electronic battlefield.

The capstone Army UAS publication is, FM 3-04.115, *Army Unmanned Aircraft Systems Operations*, dated July 2009. This study extracts two major contributions from

2666 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

this publication. First, *Army Unmanned Aircraft Systems Operations* identifies the susceptibility of UAS CDLs to disruption by EMI and friendly EW jamming systems. Second, FM 3-04.115 is the only publication that addresses counter-UAS threats and how enemy forces may attack all classes of UAS. It addresses multiple conventional counter-air threats but it is also identifies the potential for an EA (Headquarters, Department of the Army 2009a, 34).

UAS CDL susceptibility to EMI, coupled with the militant request for EW assistance, presents a reasonable direction for counter-UAS development. This study was unable to find any evidence of EA against UAS. The relative age of Man-Portable and Tactical UAS technology has limited their use on an electronic battlefield and these systems are largely untested against EW threats. Reason dictates that if UAS CDLs are susceptible to passive EMI, they are also vulnerable to an active EA.

In discussing disruption due to EMI, FM 3-04.115 states, "UAS operations are susceptible to interference from military and civilian communications systems. Terrestrial microwave systems using high energy directional antennas (MSE and tropospheric systems employed by Army and Marine units) may cause significant frequency interference problems and should be avoided (Department of the Army 2009a, 43)." These high-energy communications systems are common in major population centers and on an increasingly technologically dependant battlefield. This study continues to examine EMI on UAS CDLs and implications of such interference throughout this chapter.

Army Unmanned Aircraft Systems Operations discussed EW threats against UAS in general terms. Although it identifies the potential threat of EW systems, it fails to identify possible means to conduct an EA against UAS. It states, "UAS may be subjected

2667 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to offensive EW, computer network attacks, computer network exploitation, and signal intelligence exploitation (Department of the Army 2009a, 43)."

This study examined Joint, multi-service, and Army publications to identify perceived threats, threat mitigations, and employment considerations for all classes of UAS. Multiple manuals contribute to the discussion of these aspects, but no single publication adequately examines each of these topics. Tactically focused maneuver manuals such as FM 3-20.971, *Reconnaissance and Cavalry Troop,* dated August 2009, explains how UAS are effective combat multipliers and provides the ground commander with some UAS considerations. An aviation centric manual such as FM 3-04.115, *Army Unmanned Aircraft Systems Operations,* dated July 2009, identifies possible threats to UAS but it does not adequately support counter EW planning for UAS.

Organization

This study conducted an organizational review of Tactical and Man-Portable UAS units to assess their ability to plan for EW against UAS. This examination was conducted separately due to the differing command and control structure of these UAS. Units that employ Man-Portable UAS range from as large as Combined Arms Battalion (CAB) to as small as a Long Range Surveillance (LRS) teams. Man-Portable UAS operate below Joint airspace coordinating altitudes and do not require the same airspace control and control (AC2) considerations as larger platforms. Tactical UAS are Brigade level systems that may operate in support of subordinate unit operations. These systems operate above Joint airspace coordinating altitudes and require stringent AC2 measures to ensure de-confliction with manned aircraft.

2668 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Man-Portable UAS

TC 1-611, *Small Unmanned Aircraft System Aircrew Training Manual*, dated August 2006, is the primary training publication for Man-Portable UAS. This training circular standardizes Man-Portable UAS training and is a byproduct of Army Aviation adoption of UAS prepotency. Army aviation attempted to standardize Man-Portable UAS organizations and used manned aviation units as a design template. The organization built mirrors manned aviation units, but the Man-Portable UAS units lack the expertise of their manned counterparts (Headquarters, Department of the Army 2006c, 7). This lack of SMEs limits their ability to conduct detailed UAS planning.

In accordance with TC 1-611, the commander of an organization equipped with Man-Portable UAS is responsible for the training, planning, and mission execution of their combat system. The commander identifies an experienced operator to serve as the unit UAS Master Trainer and act as the technical and tactical expert in Man-Portable UAS operations. Man-Portable UAS operators must obtain and maintain a set level of proficiency by completing mission preparation training, compulsory training requirements, and a Semi-Annual Proficiency and Readiness Tests (Headquarters, Department of the Army 2006c, 10).

Similarly, commanders of manned Army Aviation units are responsible for the training, planning, and mission execution their pilots. An experienced warrant officer serves as the units Standardization Instructor Pilot (SIP), who is the technical and tactical expert in the employment of their airframe. Rated aviators must obtain and maintain a set level of proficiency by completing Readiness Level (RL) progression training,

2669 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

compulsory semi-annual training requirements, and an Annual Proficiency and Readiness Tests (APART) (Headquarters, Department of the Army 2006g).

The Man-Portable UAS organizational structure looks similar, but it fails to meet the intent of TC 1-611 due to a lack of expertise for three reasons.

First, the commander of a manned aviation unit is a rated aviator who maintains the same standards as the pilots they lead and is proficient in the employment of their combat system. Commanders of units equipped with Man-Portable UAS are unlikely operators and they receive no specific Man-Portable UAS training. They may not recognize the implications of CDL disruption or what can be done to mitigate interference.

Second, the SIP of a manned aviation unit is not only an experienced pilot. They have also received advanced training to assist their service as a standardization authority. An SIP receives additional training on techniques for training and evaluating individuals, designing comprehensive training programs, and maintaining aviation-training records. Conversely, Man-Portable UAS Master Trainers may themselves be inexperienced operators (Hicks 2008). The ability of a UAS Master Trainer to train operators on EW considerations is dependent on their individual experiences.

Lastly, rated aviators are board selected and undergo a ridged evaluation process. These professional pilots, especially warrant officers, are in career fields that ensure continuous growth throughout their service and this constant progression ensures a healthy talent pool. Man-Portable UAS operators are unit commander selections and there is no minimal requirement to become an operator. They do not receive a Military Occupation Specialties (MOS) career code and may only serve as an operator once in

2670 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

their career. Without ensuring Man-Portable UAS operators remain in the community, it is impossible to develop a healthy talent pool. This lack of collective knowledge limits the intellectual growth potential of the Man-Portable UAS organizations. This stagnant knowledge pool hampers their ability to cope with contingences, such as an EA, against their aircraft.

Tactical UAS

TC 1-600, *Unmanned Aircraft Systems Commander's Guide and Aircrew Training Manual*, dated August 2007, is the primary training publication for Tactical UAS. This TC standardizes Tactical UAS training and is a byproduct of Army Aviation adoption of UAS prepotency. Army aviation standardized Tactical UAS organizations and using manned aviation units as a design template (Headquarters, Department of the Army 2007, 7).

In accordance with TC 1-600, the commander of an organization equipped with a Tactical UAS is responsible for the training, planning, and mission execution the systems. A UAS Standardization Officer/NCO, who is often a warrant officer, assists the commander and serves as the technical and tactical expert for Tactical UAS operations. The commander may assign additional experienced Tactical UAS pilots to serve as Evaluator/Unit Trainers. The remaining pilots are either Mission Commanders or Unmanned Aircraft Crewmembers depending on their level of experience. Tactical UAS operators and rated aviators maintain similar standards. Tactical UAS pilots must complete RL progression training, compulsory semi-annual training, an Annual Proficiency and Readiness Tests (APART), and be medically cleared for flight duties (Headquarters, Department of the Army 2007, 21).

2671 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The Tactical UAS organizational structure looks similar and the expertise of its members allows for its successful operation.

First, the commander of a manned aviation unit is a rated aviator who maintains the same standards as the pilots they lead and is proficient in the employment of the combat system. Commanders of Tactical UAS units are not qualified to operate the systems, but the inclusion of a Standardization Officer/NCO mitigates their lack of experience.

Second, the SIP of a manned aviation unit is not only an experienced pilot, he/she has also received advanced training to assist their service as a standardization authority. An SIP receives additional training on techniques for training and evaluating individuals, designing comprehensive training programs, and maintaining aviation-training records. Tactical UAS Standardization Officer/NCO is either an experienced Tactical UAS operator or often a permanently grounded rated aviator. There is no additional training for a Standardization Officer/NCO. They rely upon their individual or collective experience to varying degrees of success (Hill 2010).

Lastly, rated aviators are board selected and undergo a ridged evaluation process. These professional pilots, especially warrant officers, are in career fields that ensure continuous growth throughout their service and this constant progression ensures a healthy talent pool. Tactical UAS operators enlist into the career field and must satisfactorily complete an extensive entry level training program that includes Federal Aviation Administration (FAA) ground school. Tactical UAS pilots are in the MOS 15W career field and will continue to progress throughout their service (Thomas 2006). This progression ensures the development of a healthy Tactical UAS talent pool. This pool of

2672 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

talent allows organizations to constantly grow and mature. This growth enables such organizations to cope with unplanned contingences, such as an EA, against their aircraft.

Training

This study reviewed training required to become a Tactical or Man-Portable UAS operator. The training plans have been examined separately due to the stark differences between the training programs. A Man-Portable UAS operator is not a unique MOS and the operators do not receive an ASI after qualification. Tactical UAS operators enlist into a career field they will remain in throughout their career.

Man-Portable UAS

There are no prerequisites for becoming Man-Portable UAS operators, but they should be technically savvy individuals. Man-Portable UAS operators in this study included infantrymen, fire supporters, mechanics, engineers, and cooks. In 2007, all RQ-11 Raven operators received their training during a 10-day course of instruction at Redstone Army Arsenal, Alabama. However, various alternate Raven qualification courses are now available due to an expansion of Man-Portable UAS utilization and constrained home-station training timelines (Hicks 2008).

In 2009, Man-Portable UAS operators received training at Redstone Army Arsenal, Alabama, Fort Benning, Georgia, Mobile Training Teams (MTTs), and Combat Training Centers (CTCs). The RQ-11 qualification course Memorandum of Instruction (MOI) includes UA familiarization, flight controls and EMI indicators, basic aerodynamics, mission planning, and UAS emergency procedures. RQ-11 operators

2673 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

receive a certificate of completion and an operator's qualification card once they complete the training (Hicks 2008).

The RQ-11 qualification course discusses EMI indicators and some common sources of this interference. This EMI discussion focuses on passive environmental sources such as radio towers, high-frequency antennas, meteorological interference, and self-imposed interference. The qualification course does not cover enemy threats to UAS or contingency planning for operations in an active EW environment (Hicks 2008).

Tactical UAS

Tactical UAS operators attend a 23-week qualification course at Fort Huachuca, Arizona. This Aviation Professional Training program includes a fully certified FAA ground school, aerodynamics, and meteorology is the first phase of training (Thomas 2006). They next receive training on image analysis, aviation maintenance management, use of the Aviation Mission Planning System (AMPS), and aviation safety considerations. Students transition to field operations once they complete classroom instruction. Field instruction includes establishment of a Tactical UAS operating base, UAS mission preparation, operating a Tactical UAS, and displacement of a Tactical UAS operating base (Thomas 2006).

Tactical UAS is a professional career field that offers advancement and career enhancement opportunities as operators gain experience. These operators attend military schools such as Basic Non-Commissioned Officer Course (BNCOC) and Advanced Non-Commissioned Officer Course (ANCOC) as they advance (Thomas 2006). They are competitive for leadership opportunities including Platoon Sergeant and First Sergeant positions. Senior operators may choose to become Warrant Officers as MOS 150U,

2674 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Tactical Unmanned Aerial Vehicle (TUAV) Operations Technician (Ayers 2008). This independent career field supports retention and encourages operators to remain in the UAS community.

The Tactical UAS qualification course focuses on UAS employment in support of maneuver operations and students do not study threats to UAS. The course MOI does not discuss either environmental EMI on UAS CDLs or EW threats to UAS CDLs. Interviews conducted with OCs at the NTC, Fort Irwin, California, confirmed a lack of EW education within the Tactical UAS community (Hill 2010). The NTC has identified this lack of EW education and aviation trainers will soon implement scenarios that train EW planning considerations (Hill 2010).

Material

This study examines vulnerabilities of UAS CDLs to an EA but these systems have not served on an active EW battlefield. However, publications such as FM 3-04.115, *Army Unmanned Aircraft Systems Operations,* dated July 2009, explain UAS susceptibility to EMI. Signal interference is the root cause behind both EMI on an UAS CDL and an EA against an UAS CDL, therefore the symptoms of both these events are similar. This section will review how such interference occurs and what material measures may be taken to mitigate this interference.

The primary subjects of this UAS CDL security review are *Unmanned Aerial Vehicle Study*, dated February 2003, the *Unmanned Aerial Vehicles: Background and Issues for Congress*, dated 21 November 2005, *Airspace Integration Plan for Unmanned Aviation*, dated November 2004, and *Unmanned Aircraft Systems FY05-FY09 Class A-C Accident Analysis,* dated 4 December 2009. Despite a wide variation in their production

2675 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

dates, the information in these reports is consistent and lends credence to the reliability of these reports.

UAS CDL Reliability

The intent of UAS is to be a cost effective alternative to manned aircraft and a way to prevent risking a pilot's life. Human needs and emotions such as fatigue, hunger, ambition, and fear do not bind unmanned systems. They dutifully carry out any assigned task, without regard to their survival or need for reward. Some believe they are incapable of committing human errors that often contribute to aviation accidents and there is a common perception that UAS never fail (Singer 2010, 63).

However, reports indicate that UAS are 100 times more likely to succumb to failure than their manned counterparts (Congressional Research Service 2005, 2). The most common causes for these failures are malfunctioning power plant or props, flight control malfunctions, human error, and communications failures (Office of the Secretary of Defense 2003, 39). According to those interviewed, determining the cause of communication failure or disruption is difficult but accident investigators often suspect EMI (Hill 2010).

A September 2009 report found that the MQ-1B Predators, an Air Force Theater UAS, experienced an estimated accident ration of 40 aircraft for 100,000 hours of flight time, an increase over the 30 aircraft for 100,000 hours of flight time ratio the previous year (Dunnigan 2009). The Air Force had anticipated a reduction in the MQ-1B accident rate to ratio of 15/20 aircraft for 100,000 hours of flight time as the technology matured (Office of the Secretary of Defense 2003, 34). Communications failure is the primary

2676 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

cause of 11 percent of these accidents and this rate has been consistent over time (Office of the Secretary of Defense 2003, 39).

The Army's Tactical UAS losses are even higher with the US Army Combat Readiness/Safety Center reporting 246 RQ-7 Shadow accidents during 421,071 flight hours over a four period. This equates to a Tactical UAS loss ratio of approximately 60 aircraft for 100,000 of flight time (Air Task Force 2009, 5).

It is impossible to estimate an accident to flight hour loss ratio for Man-Portable UAS due the Army not tracking these systems by flight hours. The Army tracks Man-Portable UAS by the number of missions an airframe completes, but information is available that allows us to examine their reliability. The US Army Combat Readiness/Safety Center reported 128 Class C accidents over a four-year period, 125 involving the RQ-11 and 3 involving the RQ-16 (Air Task Force 2009, 11).

However, this number is misleading due to many accidents causing less than $20,000 in damage, below the Class C accident threshold that requires an official report (Headquarters, Department of the Army 2009e, 32). Interviews conducted with a former NTC OC found that Man-Portable UAS operators experience CDL failure 5 to 10 times per week. Most of these crashed systems experience minimal damage and no accident report is required (Gaub 2010). NTC safety trends indicate that one Tactical UAS is damaged for every 90 hours of flight and one Man-Portable UAS is damaged for every 20 hours of flight (Key 2010, 16).

Communications failure was the primary cause for 15 percent of Army UAS reportable accidents (Air Task Force 2009, 6). The Army's higher communication failure

2677 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ratio is due in part to the operational environment in which Tactical and Man-Portable UAS operate.

Man-Portable UAS operators in Iraq and Afghanistan have lost airframes due to EMI causing CDLs communications failure. Units use traditional and unique methods to ensure the recovery of their UAS. One unusual technique stated, “Another thing we put on there is a bilingual label in Arabic and English that says, ‘If found, return to the nearest coalition forces base for a reward,’ We’ve had several turned in that way.” (Army Magazine 2005) Commanders consider the recovery of lost UAS a priority mission due to security and strategic message concerns. If enemy forces delve into the inner workings of a captured UAS, they may be able to exploit this information and develop countermeasures. In addition, an insurgent force may score a strategic communications victory by displaying a captured UAS in their propaganda.

The accident rate of manned aircraft is marginal in comparison to unmanned systems and even innovative immature aircraft, such as the F-22, is much more reliable than unmanned systems. An operational F-22 Raptor has an estimated loss ratio of six aircraft for 100,000 hours of flight time and the Air Force estimates two aircraft for every 100,000 hours of flight time its technology matures (Dunnigan 2009). The F-16 Fighting Falcon has a loss ratio of four aircraft for 100,000 hours of flight time but some have advocated its replacement by an armed UAS (Dunnigan 2009). The Army helicopter accident rate ranged from the loss of five aircraft for 100,000 hours of flight for the AH-64, to two aircraft for 100,000 hours of flight for the UH-60 (Lucas, Thompson, and Davis 2007, 1).

2678 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

EW Threats

The more dependent on technology a military force, the more vulnerable the force is to EW. The Army has lagged behind the rest of the services in the development of EW, but they are now building a comprehensive EW program. In March 2009, the Army established EW career fields that will develop Soldiers whose expertise is fighting in the electromagnetic spectrum.

EW is a set of measures and actions performed by conflicting sides to detect and attack enemy electronic systems for the control of forces and weapons, including high precision weapons, as well as to electronically defend one's own electronic systems and other targets from technical intelligence, jamming and non-deliberate interference (Vakin, Shustov, and Dunwell 2001, 1).

The symptoms of an EA on a UASs CDL and the results of EMI on a UAS CDL are similar. An EA against a UAS CDL is a likely threat scenario due to the CDLs susceptibility to EMI being public knowledge. This attack would come in the form of an active jammer designed to drown out the CDLs communications.

Jamming is a form of EA using an electronic device, known as a jammer, to transmit high power signal at receiver to disrupt signal quality (Vakin, Shustov, and Dunwell 2001, 1). The three forms of jamming this study reviewed is broadband noise, tone, and swept jamming (Poisel 2003, 213). These jammers each have advantages and disadvantages on the modern EW battlefield but their limiting factor is the power available to apply to the jamming signal.

The goal of noise jamming is to send a threat signal sufficient strength to "out shout" the transmitter sending the attacked frequency (Schlesinger 1961, 13). Noise

2679 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

jamming disrupts the communication waveform by inserting noise onto the receiver. The bandwidth of the signal may be as wide as the entire spectrum used by the communications system or it may occupy only a single channel (Poisel 2003, 216).

Broadband jamming is also known as full band or barrage jamming. This type of jamming can be effective against all forms of anti-jamming (AJ) communication systems (Poisel 2003, 216). This type of jamming raises the background noise level at the receiver, creating a higher noise environment for an AJ system. If the noise is increased, it makes it difficult for a communications system to operate. Effective noise jamming may reduce the range of the communications or if the noise is sufficient, the jammer may deny communication (Poisel 2003, 216). An effective noise jamming attack can disrupt UAS CDL communications and cause the UAS to execute its lost link programming.

The greatest advantage of broadband noise jamming is the simplicity of the system. A jammer operator selects a frequency band and creates as much noise as possible to degrade an entire frequency spectrum. It does not require a smart means to acquire the specific transmitting frequency or the need to chase a frequency hopping system. The greatest disadvantage of broadband noise jamming is the strength of the jamming signal. The larger the spectrum being jammed, the less power is available to create noise.

Sweep jamming, or swept jamming, occurs when narrowband noise is swept across a frequency band of interest (Poisel 2003, 235). The jammer focuses on a specific frequency and a small portion of the band around the single frequency. This sweep can jam a selected band in rapid succession and have effects similar to a barrage jammer. However, a swept jammer concentrates its full power against specific frequencies on the

2680 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

band of interest and this allows swept jammers to have greater range than broadband jammers.

The greatest advantage of swept jamming is the ability to jam a broadband while maintaining adequate power to project its signal (Vakin, Shustov, and Dunwell 2001). Timing is the key to effective sweep jamming and if timing is correct, the jammer can hop around a spectrum with sufficient power to degrade communications. Timing is also the greatest disadvantage to swept jamming. If the jammer hops the spectrum too quickly, it may not loiter on a selected frequency long enough to achieve the degradation desired (Poisel 2003, 235).

Spot jamming, or single tone jamming, occurs when a jammer concentrates all of its power on a single frequency (Poisel 2003, 229). These jammers are effective against communications systems that do not hop and are in use by the opposition. Spot jamming does not move along the frequency spectrum and this limits the utility of such jammers against modern military equipment.

The greatest advantage of spot jamming is the power available to project on its disrupting power at a target. These jammers may have greater range than systems that attack a broad frequency spectrum (Vakin, Shustov, and Dunwell 2001). The greatest disadvantage of spot jamming is its inability to target modern frequency hopping communications and the intelligence requirement of identifying the specific target frequency (Poisel 2003, 230).

Man-Portable UAS are the systems most likely to experience an EA against their CDLs. These systems operate at low altitudes and in close proximity to threat forces. Their flight profile allows enemy forces to visually or acoustically acquire and track the

2681 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

system throughout their mission. Man-Portable UAS CDLs communicate on an L-band UHF frequency that is easy to jam (Poisel 2003, 213). The CDL does not use any electronic protection (EP) such as a frequency hopping radio or a coded receiver. Lastly, the UAS uses an omnidirectional that can receive commands from any direction throughout its flight profile. The C-IED devices in Iraq and Afghanistan use this type of jammer and their tendency to jam UAS CDLs is a testament to the vulnerabilities of these systems (Gaub 2010).

Tactical UAS are less likely to experience an EA against their CDLs but it is still at greater risk than Theater UAS. These systems operational altitudes are higher than Man-Portable UAS but are often within audio or visual range of threat forces (Hill 2010). Directing a jamming signal able to disrupt Tactical UAS CDLs would likely require an advanced directional antenna in order to project and focus its signal (Wilson 2010). Tactical UAS Man-Portable UAS CDLs operates using S-band UHF/SHF frequency and although more jam resistant than the L-band, it is still vulnerable to jamming (Poisel 2003, 214). Lastly, the UA uses an omnidirectional that can receive commands from any direction throughout its flight profile but the GCS transmits its signal using a directional antenna (Hill 2010)

If a CDL experiences frequency interference, the system executes a self-recovery program known as a “lost link procedure” and attempts to reacquire the CDL from the GCS. If a Man-Portable UAS fails to reacquire its CDL, it continues its self-recovery program and attempts to return to a preprogrammed recovery point. If a Tactical UAS fails to reacquire its CDL, the operators may identify the UA as rogue and deploy the systems recovery parachute to avoid endangering manned aircraft.

2682 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Electronic Protection

EP is the subdivision of EW where military forces take action to protect personnel, facilities, and equipment from any effects of friendly or enemy use of the electromagnetic spectrum that degrade, neutralize, or destroy friendly combat capability (US Joint Forces Command 2007a, 8). Some experts refer to EP as the fixes to the faults exploited by ECM (Schlesinger 1961, 2). EP three subcategories are spectrum management, Electromagnetic (EM) hardening, and emission control. This study will focus on EM hardening of UAS as the only subcategory that is a defense measure against EA. It will also review self-protective measures such as counter-jammers (Headquarters, Department of the Army 2009c, 13) and Communications Security (COMSEC) measures (Headquarters, Department of the Army 2009b, 13).

In an unconstrained environment, vulnerabilities or flaws in military systems would be quickly repaired, but in reality, modifications take time. An aerospace engineer interviewed discussed a constant struggle to balance considerations of weight, size, form, and technological capabilities into component design (Macdonald 2010). A component designed for one system might not work for another system due to variation in design parameters and space available on a given airframe. EP components designed for use in Tactical UAS might be too large or heavy for use in a Man-Portable UAS. EP requirements for Man-Portable UAS might not be required for a Tactical UAS due to its higher operational altitude. Designers must consider the compromise of all these parameters and cost when developing new systems (Macdonald 2010).

Designing equipment that protects personnel, facilities, and equipment by filtering, attenuating, grounding, bonding, and shielding against undesirable effects of

2683 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

EM energy is hardening(US Joint Forces Command 2007a, 24). EM hardening is a design consideration for all UAS and hardening is one of the key differences between civilian and military UAS (Macdonald 2010). All military electronic equipment receives some hardening such as filtering, attenuating, grounding, and bonding during the production process (Wilson 2010). Most military systems receive some degree of shielding but the amount varies depending on the system. EM shielding can drastically increase the weight of a system and weight is a major concern for aircraft designers (Macdonald 2010).

Systems at risk from EW may execute a preemptive attack against a threat using defensive EA. These measures use the electromagnetic spectrum to protect personnel, facilities, capabilities, and equipment. A vulnerable system conducts a defensive EA to deny an enemy the use of the electromagnetic spectrum to attack the system (Headquarters, Department of the Army 2009c, 13). This fix to system vulnerability is referred to as electronic counter-countermeasures (ECCM) (Schlesinger 1961, 55). A common defensive EA component designed for aircraft is a counter-jammer.

An airborne counter-jammer jams in the same manner as a ground based system. They detect a jamming signal directed against an aircrafts communications system and transmit a counter-jamming signal toward the threat jammer (Puttre 2004, 57). Various self-protection electronic systems are currently available and some larger UAS have tested systems such as the AN/ULQ-21 (Puttre 2004, 67). It is very difficult to develop a completely effective ECCM system due to the dynamic nature of EW. Military forces may invest millions of dollars and an incredible amount of time to develop an ECCM that is obsolete soon after fielding. ECCM equipment often countered by electronic counter-

2684 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

counter countermeasures (ECCCM) and countering portion of the ECCM term can be carried to the ridiculous extreme (Schlesinger 1961, 55).

An overarching EW philosophy is that designers cannot make a communications system jam-proof but they can make a communications system jam-resistant. The ability to jam communications or the ability to resist jamming is a question of power. If sufficient power is available, any frequency within the electromagnetic spectrum can be jammed (Wilson 2010).

It would be difficult for a Man-Portable or Tactical UAS to produce sufficient power to resist an EA. Most Man-Portable UAS are battery powered and do not have the capability to produce their own power. Any power diverted for electronic self-protection would drastically affect their mission (Hill 2010). A Tactical UAS generates the power required to operate its systems but its ability to support additional power requirements is questionable (Hill 2010). The power production capability of a UAS is limited and the power potential of a UAS counter-jammer will be equally limited.

Denying unauthorized forces information of value that might be derived from the possession and study of telecommunications is COMSEC. These protective measures mislead or deny unauthorized persons attempting to interdict friendly communication (Headquarters, Department of the Army 2009b, 253). UAS program offices are working to improve COMSEC by applying cryptographic measures (Jensen 2010). The emphasis of these COMSEC improvements is UAS VDLs due to the publicized security breach of UAS video security by insurgents in Iraq (Gorman, Dreazen, and Cole 2009). The development of some of this COMSEC equipment is complete and fielding is ongoing (Hill 2010).

2685 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

These COMSEC systems encrypt a communications signal with a code prior to transmission and the receiver must decrypt the signal with a key to interpret the information. Coding communications does provide some EP to the transmitted signal. A smart jammer attempting to hop over a specific signal will fail unless it has the correct timing and frequencies (Poisel 2003, 237). This does not mean that a coded signal is jam-proof but it is more jam resistant. Some forms of jamming, such as broadband jamming, are not dependant on timing or frequency specificity. If enough power is available, a jammer can jam any frequency along the spectrum it is targeting (Poisel 2003, 214).

This chapter began with an extensive review of the primary Man-Portable and Tactical UAS. It analyzed existing Joint and Army doctrine, UAS organizational structure, UAS operator training, and materials that influence UAS CDL security. Each of these components play a part in UAS CDL vulnerabilities but the material aspect has the greatest degree of influence. This study has shown that UAS CDLs are susceptible to EMI and that threat technology is available to attack these flaws making the UAS vulnerable. Measures are available that provide some EP to improve the security of these systems and electronic self-protective devices could be incorporated. These modifications must account for factors such as weight, size, form, technological capabilities, and cost into any modification design. Lastly, this study found that no communications signal is jam-proof weight but designers can develop a system that is resistant to jamming.

CHAPTER 5

CONCLUSION AND RECOMMENDATIONS

> [Y]ou may fly over a land forever; you may bomb it, atomize it, pulverize it and wipe it clean of life--but if you desire to defend it, protect it, and keep it for civilization, you must do this on the ground, the way the Roman legions did, by putting your young men into the mud.
>
> — T. R. Fehrenbach

Conclusions

The procurement and utilization of UAS has exploded globally and these systems have changed the face of 21st century warfare. They are a mainstay on the modern battlefield gathering intelligence, observing key terrain, and targeting threat forces. Time will tell if the world is experiencing an UAS RMA or if these weapons are products of simple innovation. What is clear is the faith the US government has placed in UAS and their intent to lead the global development of this technology.

Reliability of the UAS communications structure is a major concern and failure of CDL communications due to EMI has resulted in numerous UAS accidents. The omnidirectional antennas the aircraft uses to establish the CDL leaves the system open to interference. Environmental EMI from communications systems produce sufficient energy to disrupt CDLs and are responsible for 15 percent of Army UAS accidents (Air Task Force 2009, 6). Man-Portable UAS CDL experience communications failure more frequently but accurate statistics are not available due to lack of reporting (Gaub 2010).

An adversary can exploit this susceptibility to EMI by conducting an EA against the CDL. The indicators of an EA and the symptoms of EMI disrupting UAS CDLs are similar. Jammers capable of disrupting CDLs may be simple range omnidirectional

2687 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

systems or smart systems that can project a signal far away from the transmitter. Interviews conducted confirmed that any communications signal can be jammed if the appropriate technique is used and sufficient power is available (Wilson 2010). Simple jammers are easy to make and these improvised jammers can attack UAS CDLs.

This chapter presents the findings and recommendations of this study using the doctrine, organization, training, and material portions of the DOTMLPF construct. These findings and recommendations are not all inclusive, but they do present the key issues that require attention to shape the future force.

Doctrine

This study's review focused the adequacy of Joint and Army doctrine to prepare for EW. The Joint doctrine review examined the establishment of a common operational language, Joint UAS employment planning, and considerations for UAS CDL protection. This study took a different approach reviewing Army publications and split its focus into two areas. First, this study examined Army maneuver doctrine to determine the adequacy of employment planning and considerations when integrating UAS into operations. Second, the study examined how well Army doctrine addresses EW threats to UAS operations.

The Joint community has failed to establish a language. Development of Joint terminology is the responsibility of US Joint Forces Command (USJFCOM) but this process is complicated due to the dynamic nature of UAS innovation. Operators and non-operators alike should clearly understand Joint terminology. The language must be ridged enough to minimize ambiguity but retain the flexibility that allows for system innovation

2688 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

and growth. Clearly defining classes is critical, especially if findings demonstrate that some classes are more susceptible to EW.

The failure to establish flexible Joint terminology has resulted in continuous changes in UAS classifications. There has been at least five different UAS naming conventions, and at one time the Air Force, Army, and Marines all used service-specific terminology. The *FY2009–2034 Unmanned Systems Integrated Roadmap,* dated April 2009, contains the most recent UAS categories. It specifies groupings based on aircraft specifications and performance. This group identification is of little value to a non-operator who does not know the specifications and performance parameters of a specific UAS (Department of Defense 2009, 110). It also lacks flexibility and the fielding of new micro UASs will require a revised terminology.

This study used the UAS classifications found FM 3-04.15, *Multi-Service Tactics, Techniques, and Procedures for the Tactical Employment of Unmanned Aerial Systems,* dated 3 August 2006, which establishes three classes based on a systems operational environment and general system capabilities. It classifies systems as Man-Portable UAS, Tactical UAS, and Theater UAS. These general groupings allow non-operators to understand system capabilities but their general description may lack the specificity some desire.

Joint planning considerations for UAS employment and considerations for CDL protection within the JPs is acceptable. There is room for improvement but the newest manual, JP 3-30, *Command and Control for Joint Air Operations,* dated 12 January 2010, is excellent.

2689 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

This study then conducted a review Army maneuver publications to determine their understanding of UAS capabilities and limitations. Maneuver forces have embraced UAS and they have a good understanding of its capabilities. They integrate unmanned systems in all operations: offensive, defensive, and tactical enabling. However, these forces lack a general understanding of UAS limitations and survivability planning considerations. They do not stress UAS dependence on uninterrupted communications, their susceptibility to EMI, or their vulnerability to EW. The only maneuver publication that addresses UAS limitations is FM 3-20.971, *Reconnaissance and Cavalry Troop*, dated August 2009. *Reconnaissance and Cavalry Troop* discusses their vulnerability to enemy fire, acoustic signature, and dependence on LOS communications.

This study next examined the adequacy of UAS threat planning. The primary document for this review was FM 3-04.115, *Army Unmanned Aircraft Systems Operations*, dated July 2009, the Army's capstone UAS planning publication. *Army Unmanned Aircraft Systems Operations* is the only Army publication that addresses both UAS CDL susceptibility to EMI and threats to UAS (Headquarters, Department of the Army 2009a). However, most of the threats identified are conventional and EW threats against UAS are mentioned just once in FM 3-04.115. This study finds that planning considerations and threat mitigation to improve UAS survivability against EW is inadequate.

Other Army aviation manuals, such as FM 3-04.126, *Attack Reconnaissance Helicopter Operations*, February 2007, is an excellent template for improvement. *Attack Reconnaissance Helicopter Operations* dedicates an entire appendix to planning

2690 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

considerations for aircraft survivability from a variety of threats, unlike the few paragraphs in *Unmanned Aircraft Systems Operations*.

Organization

This study examined the organizational structure of Man-Portable and Tactical UAS units to determine if the structure is adequate for EW planning. Aviation branch is the prepotency for UAS and they have progressively standardized UAS operations. Aviation branch has organized UAS units under the same design as their manned units. This has produced mixed results depending on the airframe.

It is unrealistic for units using Man-Portable UAS to mirror the manned aircraft organizational design. These units lack the SMEs found either manned aircraft or specialized UAS units. These units do not have leaders trained as UAS operators and unit UAS Master Trainers may themselves be inexperienced (Gaub 2010). This lack of experts limits their ability to identify indicators of EW or plan to counter an EA. Man-Portable organizations must expand their knowledge base to improve their EW planning capacity.

Tactical UAS units mirror their manned counterparts well. Aviation branch has exerted greater control over these units since their assimilation from Military Intelligence branch. These specialized UAS units have are standardized and professionals in the aviation community. Commanders of Tactical UAS units are not operators, but they have numerous SMEs advisors to mitigate their lack of training. These SMEs are capable of coping with and plan to counter EW if properly trained.

A ridged quality control process ensures Tactical UAS operators are thoroughly vetted professionals. Requirements for enlisting as a Tactical UAS operator are high and

2691 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

these Soldiers enter a career field that ensures continued progression. This ensures that only quality Soldiers receive training as an operator and keeping operators in the community ensures a consistently healthy talent pool (Thomas 2006).

Training

This study examined the training Man-Portable and Tactical UAS operators receive to identify EW training requirements. Training for these operators is different due to their specific operational environments.

Qualification training for Man-Portable UAS operators is very good. Soldiers from various MOSs and skill levels receive training by quality civilian and military trainers. Infantrymen, fire supporters, mechanics, engineers and cooks often train as Man-Portable UAS operators. These Soldiers attend a 10-day qualification course that focuses on learning about their UA, flight controls and EMI indicators, basic aerodynamics, mission planning, and UAS emergency procedures. The qualification course covers environmental forms of EMI, but does not discuss EW threats to aircraft survivability (Hicks 2008). Once qualified, operators receive a certificate of course completion but do not receive an ASI.

Initial entry training for Tactical UAS operators is excellent. The 23-week initial entry training course includes a fully certified FAA ground school, aerodynamics, meteorology, image analysis, aviation maintenance management, use of the AMPS, and aviation safety considerations (Thomas 2006). One critique of the initial entry course is an absence of instruction on threats to UAS survivability and counter EW planning.

Tactical UAS operators train as professionals entering a community through which they progress throughout their career. Unlike Man-Portable UAS operators, these

2692 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Soldiers attend developmental military schooling such as the Army's Noncommissioned Officer Course (ANCOC) as they advance, and will have leadership opportunities (Thomas 2006).

Material

This study examined the vulnerabilities of UAS CDLs to an EA. These systems have not been exposed to a highly saturated EW battlefield due to their recent development but findings can be extracted by their performance against other forms of interference. The root cause of both EMI on an UAS CDL and an EA against an UAS CDL is signal interference. UAS reaction to either EMI or an EA will be similar due to both being a result of signal interference. Disruption of UAS CDLs is reflected in a systems reliability and accident rate.

This study found the reliability and accident rate of UAS surprising. In 2005, the Congressional Research Service issued a report that UAS have an accident rate 100 times greater than manned aircraft (Congressional Research Service 2005, 2). Accident data remained consistent throughout this study and data supports the findings of the 2005 Congressional Research Service report (Dunnigan 2009). Communications failure accounts for 11% of all Theater, Tactical, and Man-Portable UAS accidents (Office of the Secretary of Defense 2003, 39). Communications failure in Army systems accounts for 15% of all reportable accidents but most incidents of communication failure for Man-portable UAS go unreported (Air Task Force 2009, 6).

EW technology is available that exploits UAS CDL susceptibility to EMI. These EW systems disrupt CDLs by transmitting a more powerful signal than that produced by a UASs GCS. These systems are jammers that "out yell" a friendly transmitter using the

2693 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

electromagnetic spectrum to send data. This form of EA will cause signal interference similar to what CDLs experience due to EMI. This study reviewed three forms of jamming: broadband noise, tone, and swept jamming (Poisel 2003, 213).

Jamming disrupts communication waveforms by flooding a receiver with noise and any signal can be jammed with sufficient power. Effective noise jamming may reduce as systems communications range or it may completely deny communications (Poisel 2003, 216). Disruption of UAS CDLs will cause a system to execute its lost link programming and force an aircraft to depart the mission area (Gaub 2010).

It is possible to defend against an EA by using EP measures or conducting a defensive EA. EM shielding is means by which designers can improve systems susceptibility to external interference. Shielding can be effective, but it can also add significant weight to the aircraft (Macdonald 2010).

Defensive EA uses the electromagnetic spectrum to execute a preemptive attack against a threat system before it can conduct an EA (Headquarters, Department of the Army 2009c, 13). A counter-jammer is a device commonly used for defensive EA. These counter-jammers detect a jamming signal and transmit a counter-jamming signal toward the threat (Puttre 2004, 57). These improvements are plausible but one must consider second and third order effects when implementing such changes. Any modification used to improve UAS CDL security must account for factors such as weight, size, form, technological capabilities, and cost into any modification design (Macdonald 2010).

COMSEC can also increase UAS CDL security, but it may not prevent CDL jamming. COMSEC imparts a code on data when sending a signal and a key is required to translate the code on the receiving end. These protective measures mislead or deny

2694 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

unauthorized persons attempting to interdict friendly communication (Headquarters, Department of the Army 2009b, 253). Coding communications does provide some EP to the transmitted signal. A smart jammer attempting to hop over a specific signal will fail unless it has the correct timing and frequencies (Poisel 2003, 237). PEO AVN is working to improve COMSEC on all Army UAS (Jensen 2010). COMSEC does not make a signal jam-proof but it may make a signal jam resistant. If sufficient power is available, any frequency within the electromagnetic spectrum can be jammed (Wilson 2010).

Recommendations

This study used the DOTMLPF construct to focus the analytical process and it will continue to use this design when making recommendations to mitigate CDL vulnerabilities.

Doctrine

This study recommends the Joint community adopt classifications aligned with the Joint levels of war: Tactical UAS, Operational UAS, and Strategic UAS. The study recommends the addition of a fourth class, Theater UAS, to reflect systems above the Operational level but below the Strategic level, such as the MQ-9 Reaper. Using the doctrinally accepted levels of war eases ambiguity, prevents continuous redefining of classes, and allows non-operators to understand the general capabilities of a system. These descriptions may be too broad for use by operators and subcategories within these classes may be required for detailed planning.

This study recommends the Army clearly explain limitations and survivability considerations for UAS in maneuver doctrine. This community understands the benefits

2695 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of this combat multiplier but many are ignorant to their limitations. This lack of understanding may be a contributing factor to the frequency of UAS CDL disruption. These forces have been trained to utilize unmanned systems, but they must be taught how to preserve these systems.

This study recommends the Army conduct a comprehensive review of counter-UAS threats and include its findings in changes to FM 3-04.115, *Army Unmanned Aircraft Systems Operations*. The audience for the revised manual is UAS operators, planners, and leaders. *Army Unmanned Aircraft Systems Operations* must be a standalone document that is applicable to all levels of war. It must account for conventional counter-air threats and EW threats against all UAS. Doctrine must dispel the belief that UAS are expendable. No UAS is expendable and the Army must do more to improve system survivability.

Organization

This study recommends a reexamination of the intent behind current Man-Portable UAS design. It is unrealistic to expect units equipped with MAN-Portable UAS to replicated manned organizations without increases in quality control and in the number of SMEs. This lack of expertise degrades the organizations ability to cope with unforeseen threats, such as an EA.

The Army must generate a standardized screening process for Man-Portable UAS operators and establish a minimum set of requirements to receive training. UAS Master Trainers must be an experienced UAS operator that understands and can plan for threat activity. Master trainers must have enough time in service to advocate UAS limitations and survivability concerns with leadership.

2696 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

UAS operators should receive an ASI on completion of initial training and they should remain proficient throughout their careers. This will allow these systems to develop a healthy talent pool comparable to Tactical UAS. This will allow Man-Portable organizations to cope with an unplanned event, such as an AE. These recommendations will increase requirements on units equipped with Man-Portable UAS. If these changes prove too disruptive, Aviation branch must reconsider the organizational design for these units.

This study has no organizational recommendations for Tactical UAS. The manned unit design is well suited for these specialized UAS organizations.

Training

This study recommends that counter EW and airframe survivability planning considerations be included in all UAS qualification training.

Man Portable UAS is the system most likely to encounter enemy contact but these operators receive limited threat training. The Man-Portable qualification course discusses environmental EMI but it does not cover EW threats to aircraft survivability. The qualification course should stress the importance of accident reporting, especially when operators suspect EMI. Accident reporting from these systems is poor and ascertaining causes of UAS failures is difficult without this data (Gaub 2010). Lastly, those who complete the qualification course should receive an ASI and be tracked throughout their careers.

Initial entry training for Tactical UAS is excellent but it lacks sufficient threat training. Aviation branch must determine threats to UAS from small arms, Air Defense Artillery (ADA), and EW. Tactical UAS training must be updated to account for these

2697 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

threats and focus its efforts on airframe survivability. These operators must understand that their systems are not expendable and they are responsible for managing its survival.

Material

This study recommends an increased effort to improve CDL protection and security. These improvements will not be universal due to the differing airframes involved. Engineers designing modifications must consider weight, size, form, technological capabilities, and cost considerations. Improvements may not be practical if they impede on system capabilities or substantially increase unit cost. Improvements of smaller systems may be limited to passive measures such as EM shielding and application of COMSEC. Larger systems may be able to integrate active measures, such as counter-jammers, into their systems. Airborne counter-jammers, such as the AN/ULQ-21, are available but current technology may not be appropriate for Army systems (Puttre 2004, 67).

Summary

UAS CDLs are vulnerable to EA and these systems may be targeted using low tech, easy to produce, jamming weapons. Jammed UAS will not complete their assigned mission, but will execute a lost link procedure in an attempt to reestablish link (Hill 2010). Disrupted UAS may reestablish their CDLs but many crash due an inability to reconnect with their GCS. The solution to rectify these flaws will not be uniform for all airframes.

Man-Portable UAS have the greatest threat of experiencing an EA, but the size of the airframe limits EP or defensive EA design options. Any modifications to Man-

2698 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Portable UAS that increases weight or substantially raises unit cost may not be worth the effort. The solution for these systems may be improved training for operators and education for leaders. Man-Portable UAS users must plan and account for aircraft survivability when conducting pre-mission planning.

Tactical UAS are less likely to experience an EA but it is possible, especially from a sophisticated threat. The size of Tactical UAS airframes allows greater options to improve CDL protection and security. Engineers still must consider size, weight, and cost when designing modifications. An upgrade that reduces current system capabilities is inadvisable but airframe survivability must be a consideration in future designs.

This study did not focus on Theater UAS but sufficient information is available to determine that these systems are least threatened by a ground based EA. These systems are still vulnerable to EA but most likely by an airborne EW platform. The size of Theater UAS allows numerous options to improve CDL protection and security.

Military aviation is in a transitional phase. Determining the future force structure and the required equipment is a complex proposition. This transformation demands extensive research and development. US military aviation stands to remain the dominant global airpower force if their vision of the future force is correct but if their vision is incorrect, it will be fighting to regain airpower relevancy. Understanding the advantages and disadvantages of manned and unmanned aircraft is vital in determining future force structure.

Manned aircraft have a number of advantages over unmanned aviation. Statistics show that the most accident prone manned aircraft lost five aircraft for every 100,000 flight hours as opposed to the least accident prone UAS losing 40 aircraft for every

2699 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

100,000 flight hours. This lower accident rate is due to higher standards for manned aircraft design and ability of a pilot to evaluate and react to an in-flight emergency.

Manned aircraft also have a number of disadvantages when compared to unmanned systems. Combatant commanders must consider the limitations and vulnerability of pilots when assigning missions. It is unconscionable to send such airframes on a mission that has little chance of survival or a mission that presses pilots beyond human limitations. Manned aircraft are more expensive to produce and maintain than their unmanned counterparts. The weak link in manned aviation is the man.

Unmanned systems have a number of advantages over manned aircraft. The systems are unbound by human limitations. They can remain airborne for long durations, do not require life support systems, do not need to eat or sleep, and they will never say no to a mission. They may minimize friendly loss of life by conducting missions that have a minimal chance of survival.

Unmanned systems also have a number of disadvantages in comparison to manned aircraft. They have a relatively high accident rate and the cost of the systems have grown exponentially. Ground based operators control these systems and they are still prone to human error. UAS operators have minimal options if an in-flight emergency occurs and such emergencies often result in the airframe being lost. Current systems are not autonomous and depend on communications with a GCS. The weak link for UAS is their dependence on continuous communications.

The best long-term solution for the military is a balanced air force structure. The military must continue to embrace UAS technology and invest in future systems. They must also remember the self-balancing nature of warfare and diversify their employment

2700 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

options. Over dependence on a single technology can leave a force unprepared for combat. In World War II, the Army Air Corps did not recognize limitations their strategic bombing doctrine and numerous lives were lost as they scrambled to produce a viable pursuit aircraft. In the Korean War, the government did not recognize the limitations of Atomic deterrence and spent months rapidly modernizing its obsolete force. In Vietnam, the Air Force had overestimated the ability of their AAMs and modified their shortsighted fighter designs with guns. The US must prepare for future combat operations against all threats whether high intensity conflict, hybrid, or asymmetric. It cannot afford to be unprepared when an unknown adversary decides to attack.

GLOSSARY

Abort. To terminate a mission for any reason other than enemy action. It may occur at any point after the beginning of the mission and prior to its completion (US Joint Forces Command 2009b, 8).

Above Ground Level (AGL). Above ground level is the height in which an aircraft is above the ground (Headquarters, Department of the Army 2007b, 19).

Acoustical Surveillance. Employment of electronic devices, including sound-recording, receiving, or -transmitting equipment, for the collection of information. (US Joint Forces Command 2009b, 8).

Air Defense Artillery (ADA). Weapons and equipment for actively combating air targets from the ground. (US Joint Forces Command 2009b, 18).

Air Surveillance — The systematic observation of airspace by electronic, visual or other means, primarily for the purpose of identifying and determining the movements of aircraft and missiles, friendly and enemy, in the airspace under observation. (US Joint Forces Command 2009b, 28).

Airspace Management. The coordination, integration, and regulation of the use of airspace of defined dimensions. (US Joint Forces Command 2009b, 27).

Barrage/Broadband Jamming. A type of electronic attack intended for simultaneous jamming over a wide area of frequency spectrum. (US Joint Forces Command 2009b, 47).

Chairman of the Joint Chiefs of Staff instruction. A replacement document for all types of correspondence containing Chairman of the Joint Chiefs of Staff policy and guidance that does not involve the employment of forces. An instruction is of indefinite duration and is applicable to external agencies, or both the Joint Staff and external agencies. It remains in effect until superseded, rescinded, or otherwise canceled. Chairman of the Joint Chiefs of Staff instructions, unlike Joint publications, will not contain Joint doctrine (US Joint Forces Command 2009b, 62).

Command and Control (C2). The exercise of authority and direction by a properly designated commander over assigned and attached forces in the accomplishment of the mission (US Joint Forces Command 2009b, 79).

Communications Jamming. Electronic measures taken to deny the enemy use of communications means (Headquarters, Department of the Army, 2004, 52)

Coordinating Altitude. A procedural airspace control method to separate fixed- and rotary-wing aircraft by determining an altitude below which fixed-wing aircraft

2702 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

will normally not fly and above which rotary-wing aircraft normally will not fly (US Joint Forces Command 2009b, 98).

Directed-Energy Warfare. Military action involving the use of directed-energy weapons, devices, and countermeasures to either cause direct damage or destruction of enemy equipment, facilities, and personnel, or to determine, exploit, reduce, or prevent hostile use of the electromagnetic spectrum through damage, destruction, and disruption. It also includes actions taken to protect friendly equipment, facilities, and personnel and retain friendly use of the electromagnetic spectrum (US Joint Forces Command 2009b, 125).

Doctrine. Fundamental principles by which the military forces or elements thereof guide their actions in support of national objectives. It is authoritative but requires judgment in application (US Joint Forces Command 2009b, 130).

Drone. A land, sea, or air vehicle that is remotely or automatically controlled (US Joint Forces Command 2009b, 131).

Electromagnetic Hardening. Action taken to protect personnel, facilities, and/or equipment by filtering, attenuating, grounding, bonding, and/or shielding against undesirable effects of electromagnetic energy (US Joint Forces Command 2009b, 135).

Electromagnetic Spectrum. The range of frequencies of electromagnetic radiation from zero to infinity. It is divided into 26 alphabetically designated bands (US Joint Forces Command 2009b, 136).

Laser Rangefinder / Designator (LRFD). A device which uses laser energy for determining the distance from the device to a place or object. A device that emits a beam of laser energy which is used to mark a specific place or object (US Joint Forces Command 2009b, 233).

Mean Sea Level (MSL). Determined based on barometric pressure, MSL altitude is the distance above where sea level would be if there were no land (Headquarters, Department of the Army 2007b, 19).

Meteorology. The study dealing with the phenomena of the atmosphere including the physics, chemistry, and dynamics extending to the effects of the atmosphere on the Earth's surface and the oceans (US Joint Forces Command 2009b, 253).

Reachback. The process of obtaining products, services, and applications, or forces, or equipment, or material from organizations that are not forward deployed (US Joint Forces Command 2009b, 331).

Remotely Piloted Vehicle. An unmanned vehicle capable of being controlled from a distant location through a communication link. It is normally designed to be recoverable (US Joint Forces Command 2009b, 338).

2703 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Spot/Tone Jamming. The jamming of a specific channel or frequency (Headquarters, Department of the Army, 2004, 187)

Sweep/Swept Jamming. A narrow band of jamming that is swept back and forth over a relatively wide operating band of frequencies (Headquarters, Department of the Army, 2004, 193)

14. ABSTRACT
This report presents the results from a review of a literature base of more than 200 publications in which eight were found to contain lists of Knowledge, Skills, Abilities, and Other Characteristics (KSAOs) for remotely piloted aircraft (RPA) crew positions, either for the purpose of system design specification or for personnel selection. The report compares KSAO lists across these studies and presents a cross reference table for them. The report also surveys past efforts to establish KSAOs in anticipation of related developments and discusses the major likely sources and nature of future changes in KSAO demand for RPA operators.

KNOWLEDGE, SKILLS, ABILITIES, AND OTHER CHARACTERISTICS

FOR REMOTELY PILOTED AIRCRAFT PILOTS AND OPERATORS

Introduction

In August 2009 Damos Aviation Services (DAS) accepted Subcontract TCN 09216 from Battelle Columbus Operations under the U.S. Army Research Office Scientific Services Program, Contract W911NF-07-D-0001 / Delivery Order 0906. This report responds to the requirement to compare and contrast current and future Knowledge, Skills, Abilities, and Other Characteristics (KSAOs) for Remotely Piloted Aircraft operators. In pursuit of this requirement relevant works were extracted from more than 40 sources beginning with the bibliographic database previously produced under this Delivery Order (Howse & Damos, 2011) and expanding with search criteria tailored to remotely piloted systems. More than 200 works were reviewed and only eight were found that are relevant to identification and evaluation of KSAOs for remotely piloted aircraft personnel and that at least elicited information from practitioners and/or subject matter experts that contributed to the identification of KSAOs.

Terminology varies considerably across services and over time within services. Even the phrases used to refer to the systems of interest are different. The phrases found in common use are: Unmanned Aerial Vehicle (UAV), Unmanned Aerial System (UAS), Unmanned Combat Air Vehicle or Uninhabited Combat Aerial Vehicle (UCAV), Remotely Piloted Vehicle (RPV), Tactical Unmanned Aerial Vehicle (TUAV), Unmanned Combat Armed Rotorcraft (UCAR), Vertical Take-off UAV (VTUAV), Ground Control System (GCS), and Common Ground Station (CGS). Because the U.S. Air Force has transitioned to universally adopting the term, Remotely Piloted Aircraft, the default term for air vehicles for this report is RPA.

There are a number of crew positions that are part of RPA systems. Not all of these have been targets of research efforts to identify or develop KSAOs. Again, there are differences in terminology across services. The crew positions that are the subject of one or more efforts cited in this paper are listed with their relevant Military Occupational Specialties (MOS), Ratings, and Air Force Specialty Codes (AFSC) are listed in Table 1.

2719 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 1. Duty positions and their associated MOS, Rating, AFSC.

Personnel Duty Positions	Service	MOS, Rating, AFSC	Basic Position Description
Air Vehicle Operator (AVO)	USA	96U	The tactical unmanned aerial vehicle (TUAV) operator supervises or operates the TUAV, to include mission planning, mission sensor/payload operations, launching, remotely piloting, and recovering the aerial vehicle.
	USA	15W	RPA operators are integral to providing Army personnel with information about enemy forces and potential battle areas. RPA operators are remote pilots of unmanned observation aircraft, who gather and study information that's required to design operational plans and tactics. The RPA operator supervises or operates the RPA, such as the Army's Shadow RPA, to include mission planning, mission sensor/payload operations, launching, remotely piloting, and recovering the aerial vehicle.
	USN	NEC 8363	Operates and navigates RPA during the enroute, mission, and return phase of flight.
	USMC	7413	External RPA operators execute the initial takeoff and final landing phases of RPA operations. They are also an integral part of all mission planning, takeoff and landing sequences, and crew coordination aspects of RPA flight.
	USAF	18X	Air Force RPA Pilots plan and prepare for missions. They review mission taskings, intelligence, and weather information, supervise mission planning, equipment configuration, and crew briefings. Also, they ensure ground station and aircraft are preflighted, inspected, loaded, and equipped for mission. RPA pilots operate aircraft and command crew, operate aircraft controls and equipment, perform, supervise, or direct navigation, surveillance, reconnaissance, and weapons employment operations. Further, they conduct or supervise training of crewmembers, ensure operational readiness of crew by conducting or supervising mission specific training. RPA Pilots also develop plans and policies, monitor operations, advise commanders, assist commanders and perform staff functions related to this specialty.
Internal Pilot (IP) - See AVO above			
External Pilot (EP)	USN	NEC 8362	Performs organizational level maintenance on aircraft systems. RPA External Pilot directly controls the flight of the RPA during launch and recovery operations by visual reference to the RPA.
	USMC	7413	
Mission Package Operator (MPO)	USA	96U	
	USA	15W	
	USN	NEC 8364	Operates the EO/IR RPA sensor during all phases of flight.

2720 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

	USAF	1UOX1	RPA Sensor Operators perform duties as a mission crew member on unmanned aerospace systems. They employ airborne sensors in manual or computer-assisted modes to actively and/or passively acquire, track, and monitor airborne, maritime and ground objects. Qualified personnel conduct operations and procedures in accordance with Special Instructions (SPINS), Air Tasking Orders (ATO) and Rules of Engagement (ROE). Crewmembers assist UAS pilots (who are commissioned officers) through all phases of employment to include mission planning, flight operations, and debriefings. Sensor Operators continually monitor aircraft and weapons systems status to ensure lethal and non-lethal application of airpower. At present, Air Force 1UOX1 specialists perform their duties on the MQ-1 Predator and the MQ-9 Reaper remotely piloted aircraft (RPA).
Sensor Operator (SO) - See MPO above			
Mission Commander (MC)	USN	NEC 8364	
Common Ground Station Operator (GSO)	USA	96H	The common ground station (CGS) operator supervises or participates in detecting, locating and tracking ground targets and rotary wing and slow moving fixed wing aircraft. The GSO receives Joint Surveillance Target Attack Radar System (JSTARS) near-real time radar imagery data, RPA imagery, Commander's Tactical Terminal/Joint Tactical Terminal (CTT/JTT) Signals Intelligence (SIGINT) data, and Secondary Imagery Dissemination (SIDS) products which are transmitted to the Common Ground Station (CGS) to provide situational development, battle management, and targeting information and imagery intelligence of value to the commander.
Intelligence Analyst	USA	96B	The intelligence analyst supervises, performs, or coordinates, collection management, analysis, processing, and dissemination of strategic and tactical intelligence.
Imagery Analyst (Enlisted)	USA	96D	The imagery analyst supervises or analyzes aerial and ground permanent record imagery developed by photographic and electronic means. Plans and recommends the use of imaging sensors for reconnaissance and surveillance missions.

2721 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Imagery Analyst (Warrant Officer)	USA	350D	Provides technical expertise and manages activities engaged in imagery interpretation activities. Acts as the chief of a platoon, section, detachment, or team performing imagery interpretation. Identifies changes of terrain, equipment locations, troop movements, or other information that contributes to intelligence. Identifies equipment by nomenclature and location to develop assessments of possible threat to U.S. forces. Develops summaries and prepares reports on imagery interpretation findings. Establishes and maintains files on imagery interpretation data, findings, records, and reports. Develops map overlays which reflect changed tactical information. Conducts intelligence briefings based on information obtained.

2722 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Historical Background

The following is an extremely brief timeline of the development and acquisition of remotely piloted systems by the U.S. military. It is included to give the reader a sense of the time-span of RPA development and the rapidity, in recent years, with which system capabilities have expanded. It will also give the reader a sense of position in the timeline for the RPA systems that were evaluated in studies cited below. A far more complete history of RPAs has been written by L.R. Newcome (Newcome, 2004). Descriptions of current and emerging RPA systems can be found in the Department of Defense's Unmanned Systems Integrated Roadmap for the years 2009 to 2034 (Department of Defense, 2009).

The first documented application of remote piloting in aviation was contained in an operating model dirigible balloon exhibited by A.J. Roberts of Australia in 1912. This balloon was radio controlled (based on designs of Nikola Tesla). The model was about 15 feet long and could be controlled at a maximum range of about 500 feet.

At the beginning of World War I Professor A.M. Low of England, whose prior efforts were related to radio range finding, developed a remotely piloted airplane for the Royal Flying Corps. He successfully developed a radio control system. However, the engine of the prototype aircraft created too much radio interference for it to function properly. The first successful flight of a practical remotely piloted dirigible balloon took place in 1924 when the Royal Aircraft Establishment's *Target* flew for 12 minutes after launch from the deck of the HMS Stronghold. This project led to the design of the *Larynx*, a monoplane designed as an unmanned aerial bomb. It first flew in 1927 but there is no record of application in combat. The DeHavilland Tiger Moth, a biplane, served as a trainer from 1932 to 1947 in England. Several hundred of these aircraft were modified as remotely piloted target aircraft (designated *Queen Bee*). A few of these were employed in coastal reconnaissance missions during World War II.

In the early 1950s the Northrop/Radioplane Company developed the YQ-1B high altitude target drone into an unmanned reconnaissance vehicle, the B-67 *Crossbow*. The YQ-1B was equipped with a warhead and a radiation seeker for attacking air defense systems. The acquisition program was cancelled in 1957 before it became operational. Another early remotely piloted air vehicle was the AQM-34A *Firebee I*. This system was a modified target drone developed by Teledyne Ryan for the U.S. Air Force. It first flew in 1960. It could autonomously fly pre-programmed reconnaissance routes and employ a variety of mission equipment modules including photographic and infrared imaging and electronic countermeasures. Firebee I was used during the Vietnam war. No records have been located regarding selection practices for system operators.

In the 1970s the Army developed the MQM-105 *Aquila*, with Lockheed Missile and Space Company as the major contractor. It was designed for multiple battlefield roles concentrating on target acquisition, designation and aerial reconnaissance. The prototype first flew in 1975 and the first full scale development air vehicle flew in 1982. It had an endurance of 3.5 hrs and carried a daylight television camera and a laser rangefinder/designator with autotracking capability. Its flight path could be preprogrammed by altering waypoints stored in the flight control system. *Aquila* was never considered a successful system and was cancelled in 1987.

2723 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The RQ-2 *Pioneer* was procured first by the Navy in 1985 from Israeli Aircraft Industries (IAI) as a naval gunnery spotting system. It has been used by the Army, Navy and Marine Corps. It has an approximate 5 hour endurance carrying electro-optical and infrared sensors.

Another system originally developed by IAI is the RQ-5 *Hunter*, originally procured from TRW in 1993 and, starting in 2003, from Northrop Grumman as the MQ-5B. *Hunter* system acquisition ended in 1996 but existing units continue to be employed and retrofitted. These systems have an endurance of 12-18 hours. In 1999 some were equipped with a laser designator and in 2003 some were modified to carry a variant of the Brilliant Anti-Tank (BAT) guided munition. They can carry a variety of munitions as wing stores and a variety of sensor packages with electro-optical and infrared capabilities. It also can carry a radio relay package to provide extended communications ranges.

The Army began procurement of the RQ-7 *Shadow* in 1999. It has an on-station endurance of approximately 6 hours and carries a variety of electro-optical and infrared sensor packages and can be equipped with a laser designator.

The MQ-1 *Predator* was developed by General Atomics for the Air Force, though Army and Navy also use them, and has been in service since 1995. This is a long-range system capable of covering very long distances to an area of operations and loitering there for as much as 14 hours before returning. Whereas the preceding systems are controlled by line-of-sight radio link, Predator uses satellite links, allowing operators to be located nearly anywhere on the globe. It can carry a variety of sensor packages in daylight and infrared modes plus a laser designator and synthetic aperture radar. It can carry various wing-mounted stores including weapons, especially modified Hellfire missiles. Variants include the MQ-1C Extended Range/ Multipurpose (ER/MP) UAS with greater range and payload, and the MQ-9 Grey Eagle.

Identifying RPA Operator KSAOs

In 1979 an effort was made by the U.S. Army Research Institute for the Behavioral and Social Sciences (ARI) to extract from the small existing cadre of remotely piloted air vehicle operators and sensor operators a set of attributes that could be used to inform the development of selection and training systems (Crumley & Bailey, 1979). The approach was to administer two survey instruments, one to air vehicle operators and the other to sensor operators, and use their responses to guide structured group interviews. The surveys were made up of 27 multiple choice items, mostly having a Likert-type format, and one open-ended item soliciting written comments. Participants in the interviews were six airframe and sensor operators and nine support personnel and supervisors. These people were serving in the development group for the *Aquila* system. The survey items were derived from system manuals and contractor job descriptions. The group interview was guided toward consensus. The responses to the survey instruments were neither tabulated nor reported.

The authors suggested there were two personality types within their subject sample. This is based on the existence of two comparatively distinct attitudes toward continued work as system operators. Personnel who preferred the air vehicle operator role were described as having an affinity for planning and logic, those who preferred the sensor operator role were described as having an affinity for uncertainty. All operators disliked having close supervision during

2724 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

missions but agreed that a third (artillery trained) person was needed in the Ground Control Station (GCS).

The authors inferred from their data that eye/hand coordination was an important component of job performance but that physical strength, endurance, hearing acuity and color vision were not required at greater than average levels. Other attributes included patience and logic. Skill in verbal communication was also indicated as important. Two specific knowledge components were identified: map reading and photo interpretation.

After a 19 year absence of any apparent attempts to identify KSAOs for unmanned aerial system operators, Biggerstaff et al. (Biggerstaff, Blower, Portman, & Chapman, 1998) conducted a more formal project to predict training performance albeit their scope was limited to the role of the RPA external pilot (EP). This study had the expressed purpose of establishing selection criteria for entrance into training for *Pioneer* RPA operators. The attributes identified were also used to assist in making recommendations for medical screening of applicants for EP and internal pilots (IP); however, this study did not establish any training or job performance predictors for any crew position other than that of EP. The EP for the Navy version of *Pioneer* has a more extensive role in system operation than in larger RPAs. For *Pioneer* the EP is in direct interactive control of the airframe for takeoffs, landings, and while the airframe is in visual range of the crew. That is, the EP operates the airframe by manipulation of a set of flight controls similar to those of a recreational radio controlled aircraft. Takeoff and landing may be accomplished on a short airstrip or by jet-assisted launch from a pedestal and landing by capture net (shipboard operations).

The authors approached the operator tasks through task analyses, field observations, interviews (structured and unstructured), and test battery trials. An initial set of critical tasks was derived from observations and interviews of EPs, IPs, mission payload operators (MPO) and other related personnel. These tasks provided the source for personal attributes posited to affect performance. A single test battery, the Computer-Based Performance Test (CBPT) was selected to measure predictor variables (Delaney, 1992). A criterion measure was formed from an unspecified composite of instructor evaluations and flight grades, on a 0-100 scale.

The derived list of attributes, according to the authors, consisted of skills only; no specific knowledge, abilities, or other attributes were included. The derived skills were likely referred to as such because their source was a sample of fully trained, successful practitioners, rather than candidates. Therefore, personal attributes imparted by prior selection and training processes are assumed to be present. These skills were: Mental reversals/rotation, estimation of time to contact, eye-hand coordination, selective auditory attention, and multitasking (psychomotor + visual). It was determined that six subtests of the CBPT would adequately measure these skills: Psychomotor (PMT), Dichotic Listening (DLT), Horizontal Tracking (HT), Digit Cancellation (DC), Manikin, and Time Estimation (TET).

It appears to be the case that performance on the test battery components operationally defined the skill set. These test battery components are neither simple nor independent. They are designed to be administered in combinations and in specific orders progressing in complexity. PMT is combined with DLT, HT with DC, and Manikin with TET. The test components were

2725 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

associated with specific abilities: PMT with multilimb coordination, DLT with divided attention, HT with perceptual motor tracking, DC with reaction time and short-term memory, Manikin with mental rotation and short-term memory, and TET with perceptual tracking. Note that the abilities associated with DC do not directly correspond to any of the identified skills but may contribute indirectly to their measurement. The authors state that DC was used as a distracter, although no rationale for this is given. It may be that without an interfering secondary task HT was insufficiently difficult to produce measurement variance. The prototype battery was administered to eight students in EP training and six practicing EPs. It is not specified whether data from all 14 subjects were used to factor analyze eight performance scores derived from the battery. A single factor, consisting of a linear combination of the eight derived performance scores, was determined and used to predict the criterion measure using linear regression. The authors recognized that eight subjects (for whom the criterion measure was available) made for a rather small sample. Their solution was to insert 3 fictitious data points, one at the extreme low end of both predictor and criterion score, one at the extreme high end of both scores, and one at the approximate midpoints of both scores. The fictitious data points placed at the extremes were placed not at the extremes of observed scores on the predictor but rather, near the extremes of possible scores on the predictor. It is not unreasonable to expect that such manipulation would have a strong effect on the outcome of the regression. A review of the plot of factor scores versus criterion scores for 11 data points indicates that if the fictitious points were removed the slope of the regression would be similar but the dispersion far greater. The actual utility of the reported adjusted R^2 of .86 is questionable.

A job analysis intended for RPA future requirements was conducted by the Army Research Laboratory Human Research and Engineering Directorate (Barnes, Knapp, Tillman, Walters, & Velicki, 2000) that used the Job Assessment Software System (JASS) to explore manpower alternatives. The primary issues considered were the need for rated aviators and for imagery and intelligence specialists in RPA crews. This study was not intended to produce any information regarding selection of personnel for training. JASS was used to elicit relative importance ratings of two reduced sets of skills and abilities for RPA operators. The reduced skill and ability sets were extracted, presumably by the authors, from the 50 that comprise the full set in the JASS application. The 50 attributes in JASS are based on 52 abilities in Fleishman's Manual for Ability Requirements Scales (Fleishman & Quaintance, 1984). The reduced attribute sets were cognitive skills and abilities judged to be related to flight and navigation tasks for air vehicle operators (AVO) and to takeoff and landing tasks for EPs. The ratings were taken from a mix of 30 soldiers and contractors who were practicing as *Hunter* AVOs, MPOs and EPs. In addition, ratings on the EP list were taken from 16 Army aviators. (These will not be further discussed here.) Reduced attribute sets for JASS were also established for intelligence analysts and imagery analysts based on task structures for each. Rating data were collected in JASS on these attribute sets from nine intelligence analysts and eight imagery analysts. The ratings for each specialty were correlated with ratings taken from the original sample of AVOs, MPOs and EPs.

The JASS structure groups the 50 abilities taken from Fleishman into 8 categories: Communication, Conceptual, Reasoning, Speed Loaded, Vision, Audition, Psychomotor, and Gross Motor. The ratings indicate that the AVOs considered the Communications group (including oral and written comprehension and oral and written expression) to be most important, followed by the Conceptual group (including memorization, problem sensitivity, spatial

2726 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

orientation, and selective attention), and the Reasoning group (deductive reasoning, information ordering and inductive reasoning). The Vision, Audition and Gross Motor groups received comparatively low importance ratings. The ratings indicate that the EPs considered the Conceptual, Vision and Psychomotor groups most important.

The authors did not attempt any evaluation of psychomotor skills in their own work for this report but did review and report the results of previous unpublished work (Hopson, 1995) in which psychomotor ability was assessed for use in selecting RPA EPs. (We have not obtained a copy of that manuscript and so must rely on the reporting of the authors.) The instrument used in that study was the Enhanced Computer Administered Test (ECAT) battery. The ECAT battery was developed by ARI and the U.S. Navy Personnel Research and Development Center (NPRDC) to evaluate candidates for augmentation of the Armed Services Vocational Aptitude Battery (ASVAB), under ARI's Project A (Oppler et al., 1992). The authors report that the unpublished study used two of nine subtests in the battery (Oppler et al. list 10 subtests in ECAT), One-Hand Tracking (also known as Target Tracking Test 1) and Two-Hand Tracking (also known as Target Tacking Test 2). The subtests were administered to 28 EP candidates in training in both Hunter and Pioneer systems, from the Army, Navy, and Marine Corps. The authors report that the unpublished work indicated a strong relationship between the One- and Two-Handed Tracking scores and failure to complete training. No statistical analysis of the data is reported.

In another application of the JASS tool, Warner and Knapp (2000) compared the current skill requirements for Army Common Ground Station Operators with projected skill requirements for an enhanced Common Ground Station in development. They also considered whether skills and abilities possessed by Intelligence Analysts and Image Analysts should be integrated into CGS personnel. JASS was administered to 41 CGS Operators (GSO) to acquire importance ratings on seven high level functions specific to their duty position in the enhanced CGS. These were:

1. Establish Comm Links
2. Display moving target indicator (MTI) track targets
3. Respond to All Source Analysis System (ASAS) tasking
4. Respond to fire support tasking
5. Correlate sensor data from RPA, Commander's Tactical Terminal (CTT), and MTI
6. Perform target analysis
7. Use intel-ops knowledge

Of the 41 operators participating, 13 had experience in the developmental enhanced CGS. Only four of the eight JASS skill categories were considered likely to be impacted in the enhanced CGS: Communication, Conceptual, Speed Loaded, and Reasoning. These four groups contain 23 of the 52 abilities listed in Fleishman's Manual for Ability Requirements Scales (Fleishman & Qaintance, 1984). The data indicate that in the Communication group skill demands were expected to decrease for all seven functions in the enhanced CGS. Skill demands for Functions 2, 3, and 4 were also expected to decrease in all four skill groups. These decreases were attributed to expected efficiencies stemming from improved user interfaces and increased automation. For Functions 1, 5, and 7 the expectation was for an increase in skill demand for the Conceptual, Speed Loaded, and Reasoning skill groups.

2727 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The authors also compared their rating data with ratings obtained earlier from Image Analysts and Intelligence Analysts. Their data indicated that for several of the abilities rated in JASS the Image Analysts and Intelligence Analysts tended to rate the requirement as high (an arbitrary rating of 3 or greater) on a greater proportion of the functions involved. This comparison is unclear at best because the function sets rated by the Imagery and Intelligence Analysts were different from the GSO function set and presumably different from each other. The authors concluded that fielding of the enhanced CGS would be expected to produce a shift in ability requirements toward cognitive and perceptual categories. It should be noted that the enhanced CGS that was in development during this study is not yet fully implemented.

In a 2003 presentation at the Military Testing Association Conference, Phillips et al., (Phillips, Arnold, & Fatolitis, 2003) described their effort to validate a selection battery for RPA operator training. This was a follow-on to Biggerstaff et al., described above. However, whereas Biggerstaff et al. developed their battery for EP selection, Phillips et al. conducted a validation of a similar battery for prediction of success in IP training. It is assumed that the validation is based on analysis of data that had been in existence for several years. The battery was administered to 39 individuals who were in IP training between 1995 and 1997. It is not clear at what point in training the battery was administered. The test battery was the same as that used in Biggerstaff et al. except the Time Estimation Test (TET) was not used. Scoring, however, was accomplished rather differently. Predictor variables were four Component Scores and an Index Score. The four Component Scores, each consisting of the mean of a set of standardized battery performance scores, were taken from the PMT, DL, HT, DC, and Manikin tests. The four Component Scores were named: Psychomotor, Multitasking-calculation, Multitasking-psychomotor, and Visuospatial. These score components were not independent. For example, from the simultaneous presentation of DL and the one-hand tracking portion of PMT (stick), the DL score was used in the Multitasking-calculation score component and the one-hand tracking (stick) portion was used in the Multitasking-psychomotor component. The mean of the four Component Scores comprised the Index Score.

Two criterion variables were used. The first, Training Performance, was the average of all test scores and flight evaluation grades in training. The second was dichotomous, attrition from training, presumably without regard to cause. Of the 39 students in the sample, six failed to complete training. These as a group had significantly lower performance on the predictor variables, all four Component Scores, and on the Index Score, as indicated by t-tests calculated using an alpha value of .05. The Index Score is a linear combination of the Component Scores. Considering only the Component Scores, the sum of the Type I error probability is .25. Attriting students did not exhibit significantly different training performance scores from non-attriting students. All four Component scores and, not surprisingly, the Index Score, significantly correlated with training performance. This is based on a univariate correlation matrix. No multivariate analysis was reported. The correlation between the Index Score and Training Performance was .59.

A selection test battery was developed for Army UAS operators in 2007 (Bruskiewicz, Houston, Hezlett, & Ferstl, 2007). The Army uses a single Military Occupational Specialty (MOS) for both AVO and MPO positions. Because they are completely cross-trained and interchangeable, a single battery can be used for training selection. This battery was not designed for any other

2728 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

UAS-related position. Development of the battery was in anticipation of the effects on UAS operator tasks and missions and, therefore, on relevant personal attributes that would result from the transfer of all Army UAS assets (except for Raven, which remains with the Infantry) from the Military Intelligence Branch to the Aviation Branch. Under the Military Intelligence branch the relevant MOS was 96U. Under the Aviation branch it is 15W.

Development of the battery began with a job analysis using the job inventory approach implemented through a Job Analysis Questionnaire (JAQ). Prior job analyses and training materials were reviewed to produce a preliminary task list with related KSAOs. These provided the base content of a draft JAQ. The draft JAQ was reviewed by subject matter experts who provided feedback on both content and structure, and was revised to produce an instrument with 135 task statements and 77 KSAO statements. The resulting JAQ was administered at five locations and generated valid responses from 75 individuals. Ten of these were subject matter experts (SME) who had particular knowledge of emerging UAS airframe and mission capabilities and who were asked to complete the JAQ with future KSAO requirements in mind. All of the remaining 65 respondents were current Army UAS operators. For the SME respondents the inter-rater agreement on importance of KSAO statements was .64, which is considered high. For the rest of the respondents the inter-rater agreement on importance of KSAO statements was .58, which is considered moderate.

Using a conservative Type I error rate of .10 the authors found nine KSAOs on which the SME subgroup differed from the rest of the respondents as indicated by the means of importance ratings. Using a more customary Type I error rate of .05, there are only four: Operation of Weapon Systems and Equipment, Operation of Sensor/Tracking Systems and Equipment, Risk Tolerance, and Deliberation. In the first two cases the SMEs produced higher mean importance ratings than the rest of the respondents. In the last two cases the SMEs produced lower mean importance ratings. The first two were Knowledge attributes that directly relate to weapon system operation. Only the SMEs had experience with weaponized UAS. The other two were both Other attributes. The lower mean SME rating of the importance of risk tolerance could be anchored in the increased level of responsibility, magnitude of consequences and emphasis on rules of engagement that attend weaponization of UAS. These differences did not impact decisions regarding assessment of the attributes, but they do provide indication of shifting demands relating to required personal attributes.

System specific knowledge is presumed to be imparted during the training process. It was therefore deemed unnecessary (and probably unproductive) to assess the Knowledge attributes in the prototype selection battery. The Skills, Abilities, and Other Characteristics were considered to be critical if they received a mean importance rating (from the whole sample) of 3.0 or higher. Of the 65 non-Knowledge KSAOs, 49 were considered critical. Responding to guidance to maximize the use of existing instruments rather than develop new ones, the authors selected four instruments that had been developed for or used in a preceding project to develop an aviator selection battery for the Army, the Selection Instrument for Flight Training (SIFT). These were: Army Aviation Biodata, Assessment for Individual Motivation, Perceptual Speed and Accuracy-Hidden Figures, and Perceptual Speed and Accuracy-Simple Drawings. Two subtests were selected from the Navy's Aviation Selection Test Battery (ASTB): Reading Comprehension and Spatial Apperception. Finally, a subtest was selected from the Navy's Performance Based

2729 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Measures (PBM) battery, the Directional Orientation Test. The combination of these into a selection battery for UAS operator training selection is believed to assess 35 of the 49 critical KSAOs, while retaining an acceptable cost of administration, particularly in terms of administration time (typically less than 2 hours).

Pilot testing was conducted on the prototype battery using 20 students in Army UAS operator training. There were no indications of psychometric deficiencies among the subtests. Intercorrelations of scores appeared to be logical and consistent with expectation. None of the correlations were high enough to preclude expectation of unique contribution to predictive validity. Review of the courses of training at that time lead to a recommended set of Criterion Measures for UAS operator training selection. These include five derived from scores on written tests in specific phases of the common core training and a Behavioral Summary Scale (BSS) to be completed by instructors on a daily basis. Three additional measures would be derived from the advanced phases of training that are system specific. These would include the score on one written exam, the number of retests required to pass the Simulator-based flight portion of training, and the number of retests required to pass the flight portion of training. In addition BSS scores would also be used.

Recently the Air Force Research Laboratory 711th Human Performance Wing (Chappelle, McDonald, & King, 2010) conducted a study to identify critical personal attributes relevant to training success and career performance for RPA sensor operators. The authors approached their work through structured interviews conducted in five venues. In the Command Interviews senior commanders were interviewed individually and in a group discussion to elicit their perceptions on RPA operational roles and on personal attributes relating to success. The authors also conducted RPA Pilot interviews and Sensor Operator interviews, and Multidisciplinary Group interviews. Finally, Instructor Interviews were conducted in concert with observation of simulator-based training scenarios. A total of 69 RPA operators participated. These represented four subgroups: Commanders, instructors, pilots, and sensor operators.

Notes from the structured interviews were consolidated and a list of 130 attributes was extracted. After elimination of redundancies and elimination of knowledge and skill attributes that resulted from system training, the remaining attributes were reviewed to determine the number of subgroups that identified them as critical. Those so identified by three of the four subgroups of participants were retained. The remaining 21 critical attributes were placed into one of four groups: physical health, cognitive aptitude, personality traits, and motivation.

A related study (Chappelle, McDonald, & McMillan, 2011) was conducted to identify critical personal attributes relevant to training success and career performance for RPA pilots. This approach was based on structured interviews starting with SMEs, then senior commanders. The authors conducted individual and group interviews with RPA pilots, received 4 hrs of pilot training and conducted group interviews with pilots and sensor operators. They also interviewed a group of flight surgeons. A total of 82 individuals participated. Notes were consolidated and a preliminary list of 130 attributes was extracted (interestingly, the same number as in the previous study). Redundancies, and the knowledge- and skill-based attributes were removed. The resulting list of 21 attributes was nearly identical to that of the previous study. At this point there occurred a novel change in the process. The 21 attributes were sorted into four “domains”:

2730 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

cognitive aptitudes, intrapersonal traits, interpersonal traits, and motivational traits. Three of the four correspond to the groups used in the previous study. Physical health was eliminated and apparently the personality traits group was split into intra- and inter-personal traits. The 21 attributes from the final list were sorted into the four "domains" at which point they are referred to as "facets." Each facet was given a set of "distinct attributes." These correspond closely with the descriptions used in the previous study. What had been attributes became facets. What had been descriptions became attributes. In order to make sense of any comparison of KSAOs across studies, this shift in terminology will be ignored and the "facets" will be treated as attributes.

Comparison of RPA Operator KSAOs

Eight publications that in some form produced KSAOs for RPA crew positions were reviewed in the previous section. The KSAO lists from each of these are presented in Tables 3 through 10. As a baseline reference, and because of commonality with several of the attribute lists, Table 2 presents a list of the Abilities attributes contained in Fleishman's Manual for the Ability Requirements Scales. In Table 2 there are Abilities only, no Knowledge, Skills or Other Characteristics. Fleishman constructed this list with the goal of eventually developing a global taxonomy that could describe any task in terms of personal attributes required to complete it. This was to be a tool for comparing tasks and sorting them into categories. The list presented here contains the names of 52 human abilities with definitions for each. They can be seen still in the far larger and more complex lists of the Occupational Information Network (O*NET). The numbering of these is the same as used by Fleishman. For Job Analysis, the use of an attribute taxonomy allows greater ability to generalize across studies and behavioral situations than if attributes are named and operationally defined uniquely in every instance. That can lead to overly complex attribute labels and wide variance among job evaluators in redundancy and specificity. Additionally, it can create conditions in which attributes with the same or very similar names may refer to very different capabilities. The attribute set in Table 2, however, is far from global, covering only a portion of one major domain, abilities, that are the concern of job and task analysts.

Table 3 lists the Skills, Abilities and Other Characteristics that appeared to be contained in the report by Crumley and Bailey (1979). This report predates Fleishman's taxonomy and the work reported by them was not intended to provide a complete job analysis for RPA operators. It is the earliest example of any attempt to identify personal attributes that was found. This list contains only eight entries: Two Skills, four Abilities and two Other Characteristics. The authors did not offer any operational definitions of these attributes. They are numbered approximately in the order in which they are mentioned in the text.

Table 4 lists the attribute list derived from Biggerstaff et al. (1998). It is even shorter, with only 5 entries, all considered Skills. The operational definitions appear to be the test tasks themselves rather than qualities intrinsic to job related tasks. It appears that in this case the development of predictor measures for training performance may have been the reverse of the usual process: The personal attributes were derived from the available assessment instruments and assigned to the job of RPA External Pilot.

2731 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The list in Table 5, from Barnes at al. (2000), is longer, with 50 attributes listed and numbered in the order in which the authors listed them. The correspondence with Fleishman's taxonomy is nearly perfect, not surprisingly since the survey tool used (JASS) is directly derived from Fleishman. The developers of JASS re-ordered the abilities and grouped them logically. They also changed a few of the definitions to make them more readable and intuitive. For example, their ability # 23, Choice Reaction Time, corresponds with Fleishman's #22, Response Orientation. This correspondence becomes clear only when the definitions are compared.

Table 6 lists 50 attributes that were identified by Warnes and Knapp (2000). These are identical to those in Table 5 because the same tool, JASS, was employed. Where Barnes et al. concentrated on AVO and EP jobs, Warnes and Knapp concentrated on the job of GSO.

The attribute list from Phillips et al. (2003) is the shortest with only four entries. As with Biggerstaff et al. (1998), it appears that the assessment instruments were more the source of attribute definition than either the job or tasks. Table 7 lists these and shows that they are identical to those in Biggerstaff et al. except for the absence of time estimation.

Things are very different in Table 8, which lists the attributes identified by Bruskiewicz et al. (2007) from a job analysis performed on both AVO and MPO positions. This list contains 77 attributes: 12 Knowledge, 6 Skills, 25 Abilities, and 38 Other Characteristics. They are numbered in the order in which the authors listed them. This large set, covering all four attribute domains exists largely because they were produced by the only study on KSAOs for RPA operators that performed a complete process for KSAO identification. The danger attendant to their approach is that there is not a strong connection to any particular taxonomy, and so many of the attributes and their definitions may be ad-hoc. Therefore, it becomes difficult to compare these with attributes listed in other works.

Table 9 presents 21 attributes identified by Chappelle at al. (2010) for MPO positions, including seven Abilities and 14 Other characteristics. Although the authors reported that Knowledge and Skill attributes had been identified, their screening process eliminated them. The attributes are numbered in the order in which the authors listed them. These attributes, derived entirely from interviews with practitioners, are largely ad hoc with little correspondence to KSAOs identified in other works. They also tend to be vague and poorly defined.

Table 10 presents the 21 attributes identified for AVOs by Chappelle at al. (2011). There is a fair amount of correspondence between this and the previous list in the attribute names. The definitions, however are in some cases identical and in others radically altered. In addition, they have been reordered. This makes comparison even between these two related studies problematic.

2732 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 2. Attribute list from Fleishman's Manual for the Ability Requirements Scales (Fleishman & Quaintance, 1984).

	Attribute Name	Description
Abilities		
1	Oral Comprehension	Ability to understand spoken English words and sentences.
2	Written Comprehension	Ability to understand written sentences and paragraphs.
3	Oral Expression	Ability to use English words or sentences in speaking so others will understand.
4	Written Expression	Ability to use English words or sentences in writing so others will understand.
5	Fluency of Ideas	Ability to produce a number of ideas about a given topic.
6	Originality	Ability to produce unusual or clever ideas about a given topic or situation. It is the ability to invent creative solutions to problems or to develop new procedures to situations in which standard operating procedures do not apply.
7	Memorization	Ability to remember information, such as words, numbers, pictures, and procedures. Pieces of information can be remembered by themselves or with other pieces of information.
8	Problem Sensitivity	Ability to tell when something is wrong or is likely to go wrong. It includes being able to identify the whole problem as well as the elements of the problem.
9	Mathematical Reasoning	Ability to understand and organize a problem and then to select a mathematical method or formula to solve the problem. It encompasses reasoning through mathematical problems to determine appropriate operations that can be performed to solve problems. It also includes the understanding or structuring of mathematical problems. The actual manipulation of numbers is not included in this ability.
10	Number Facility	Involves the degree to which adding, subtracting, multiplying, and dividing can be done quickly and correctly. These can be steps in other operations, such as finding percentages and taking square roots.
11	Deductive Reasoning	Ability to apply general rules to specific problems to come up with logical answers. It involves deciding if an answer make sense.
12	Inductive Reasoning	Ability to combine separate pieces of information, or specific answers to problems, to form general rules or conclusions.
13	Information Ordering	Ability to follow correctly a rule or set of rules to arrange things or actions in a certain order. The rule or sets of rules used must be given. The things or actions to be put in order can include numbers, letters, words, pictures, procedures, sentences, and mathematical or logical operations.
14	Category Flexibility	Ability to produce many rules so that each rule tells how to group a set of things in a different way. Each different group must contain at least two things from the original set of things.
15	Speed of Closure	Involves the degree to which different pieces of information can be combined and organized into one meaningful pattern quickly. It is not known beforehand what the pattern will be. The material may be visual or auditory.
16	Flexibility of Closure	Ability to identify or detect a known pattern (such as a figure, word, or object) that is hidden in other material. The task is to pick out the disguised pattern.

2733 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

17	Spatial Orientation	Ability to tell where you are in relation to the location of some object or to tell where the object is in relation to you.
18	Visualization	Ability to imagine how something will look when it is moved around or when its parts are moved or rearranged. It requires the forming of mental images of how patterns or objects would look after certain changes, such as unfolding or rotation. One has to predict how an object, set of objects or pattern will appear after the changes are carried out.
19	Perceptual Speed	Involves the degree to which one can compare letters, numbers, objects, pictures or patterns, quickly and accurately. The things to be compared may be pictures or patterns, quickly and accurately. The things to be compared may be presented at the same time or one after the other. This ability also includes comparing a presented object with a remembered object.
20	Control Precision	Ability to move controls of a machine or vehicle. This involves the degree to which these controls can be moved quickly and repeatedly to exact positions.
21	Multilimb Coordination	Ability to coordinate movements of two or more limbs (for example, two arms, two legs or one leg and one arm), such as in moving equipment controls. Two or more limbs are in motion while the individual is sitting, standing or lying down.
22	Response Orientation	Ability to choose between two or more movements quickly and accurately when two or more different signals (lights, sounds, pictures) are given. The ability is concerned with the speed with which the right response can be started with the hand, foot or other parts of the body.
23	Rate Control	Ability to adjust an equipment control in response to changes in the speed and/or directions of a continuously moving object or scene. The ability involves timing these adjustments in anticipating these changes. This ability does not extend to situations in which both the speed and direction of the object are perfectly predictable.
24	Reaction Time	Ability to give one fast response to one signal (sound, light, picture) when it appears. This ability is concerned with the speed with which the movement can be started with the hand, foot or other parts of the body.
25	Arm-Hand Steadiness	Ability to keep the hand or arm steady. It includes steadiness while making an arm movement as well as while holding the arm and hand in one position. This ability does not involve strength or speed.
26	Manual Dexterity	Ability to make skillful coordinated movements of one hand, a hand together with its arm, or two hands to grasp, place, move or assemble objects, such as hand tools or blocks. This ability involves the degree to which these arm-hand movements can be carried out quickly. It does not involve moving machine or equipment controls, such as levers.
27	Finger Dexterity	Ability to make skillful coordinated movements of the fingers of one or both hands and to grasp, place or move small objects. This ability involves the degree to which these finger movements can be carried out quickly.
28	Wrist-Finger Speed	Ability to make fast, simple repeated movements of the fingers, hands and wrists. It involves little, if any, accuracy or eye-hand coordination.
29	Speed of Limb Movement	Involves the speed with which a single movement of the arms or legs can be made. This ability does not include accuracy, careful control or coordination of movement.

2734 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

30	Selective Attention	Ability to concentrate on a task one is doing. This ability involves concentrating while performing a boring task and not being distracted.
31	Time Sharing	Ability to shift back and forth between two or more sources of information.
32	Static Strength	Ability to use muscle force in order to lift, push, pull or carry objects. It is the maximum force that one can exert for a brief period of time.
33	Explosive Strength	Ability to use short bursts of muscle force to propel oneself or an object. It requires gathering energy for bursts of muscle effort over a very short time period.
34	Dynamic Strength	Ability of the muscles to exert force repeatedly or continuously over a long time period. This is the ability to support, hold up or move the body's own weight and/or objects repeatedly over time. It represents muscular endurance and emphasizes the resistance of the muscles to fatigue.
35	Trunk Strength	Involves the degree to which one's stomach and lower back muscles can support part of the body repeatedly or continuously over time. The ability involves the degree to which these trunk muscles do not fatigue when they are put under such repeated or continuous strain.
36	Extent Flexibility	Ability to bend, stretch, twist, or reach out with the body, arms or legs.
37	Dynamic Flexibility	Ability to bend, stretch, twist, or reach out with the body, arms and/or legs, both quickly and repeatedly.
38	Gross Body Coordination	Ability to coordinate the movement of the arms, legs and torso together in activities in which the whole body is in motion.
39	Gross Body Equilibrium	Ability to keep or regain one's body balance or stay upright when in an unstable position. This ability includes maintaining one's balance when changing direction while moving or standing motionlessly.
40	Stamina	Ability of the lungs and circulatory systems of the body to perform efficiently over long time periods. This is the ability to exert oneself physically without getting out of breath.
41	Near Vision	Capacity to see close environmental surroundings.
42	Far Vision	Capacity to see distant environmental surroundings.
43	Visual Color Discrimination	Capacity to match or discriminate between colors. This capacity also includes detecting differences in color purity (saturation) and brightness (brilliance).
44	Night Vision	Ability to see under low light conditions.
45	Peripheral Vision	Ability to perceive objects or movements towards the edges of the visual field.
46	Depth Perception	Ability to distinguish which of several objects is more distant from or nearer to the observer or to judge the distance of an object from the observer.
47	Glare Sensitivity	Ability to see objects in the presence of glare or bright ambient lighting.
48	General Hearing	Ability to detect and to discriminate among sounds that vary over broad ranges of pitch and/or loudness.
49	Auditory Attention	Ability to focus on a single source of auditory information in the presence of other distracting and irrelevant auditory stimuli.
50	Sound Localization	Ability to identify the direction from which an auditory stimulus originated relative to the observer.
51	Speech Hearing	Ability to learn and understand the speech of another person.
52	Speech Clarity	Ability to communicate orally in a clear fashion understandable to the listener.

2735 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 3. Attribute list from Crumley & Bailey, 1979.

	Attribute Name	Description
	Skills	
1	Map Reading	
2	Photo Interpretation	
	Abilities	
3	Oral Comprehension	
4	Situational Awareness	
5	Oral Expression	
6	Multilimb Coordination	
	Other Characteristics	
7	Affinity for Planning and Logic	
8	Affinity for Uncertainty	

2736 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 4. Attribute list from Biggerstaff et al., 1998.

	Attribute Name	Description
	Skills	
1	Mental reversals/rotation	Manikin test performance
2	Estimation of time to contact	Time Estimation Test (TET) performance
3	Eye-hand coordination	Horizontal Tracking (HT) Test performance
4	Selective auditory attention	Dichotic Listening Test (DLT) performance
5	Multitasking (psychomotor + visual)	Psychomotor Test (PMT) performance

2737 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 5. Attribute list from Barnes et al., 2000.

	Attribute Name	Description
	Abilities	
1	Oral Comprehension	Ability to understand spoken English words and sentences.
2	Written Comprehension	Ability to understand written sentences and paragraphs.
3	Oral Expression	Ability to use English words or sentences in speaking so others will understand.
4	Written Expression	Ability to use English words or sentences in writing so others will understand.
5	Memorization	Ability to remember information, such as words, numbers, pictures, and procedures. Pieces of information can be remembered by themselves or with other pieces of information.
6	Problem Sensitivity	Ability to tell when something is wrong or is likely to go wrong. It includes being able to identify the whole problem as well as the elements of the problem.
7	Originality	Ability to produce unusual or clever ideas about a given topic or situation. It is the ability to invent creative solutions to problems or to develop new procedures to situations in which standard operating procedures do not apply.
8	Fluency of Ideas	Ability to produce a number of ideas about a given topic.
9	Flexibility of Closure	Ability to identify or detect a known pattern (such as a figure, word, or object) that is hidden in other material. The task is to pick out the disguised pattern.
10	Selective Attention	Ability to concentrate on a task one is doing. This ability involves concentrating while performing a boring task and not being distracted.
11	Spatial Orientation	Ability to tell where you are in relation to the location of some object or to tell where the object is in relation to you.
12	Visualization	Ability to imagine how something will look when it is moved around or when its parts are moved or rearranged. It requires the forming of mental images of how patterns or objects would look after certain changes, such as unfolding or rotation. One has to predict how an object, set of objects or pattern will appear after the changes are carried out.
13	Inductive Reasoning	Ability to combine separate pieces of information, or specific answers to problems, to form general rules or conclusions.
14	Category Flexibility	Ability to produce many rules so that each rule tells how to group a set of things in a different way. Each different group must contain at least two things from the original set of things.
15	Deductive Reasoning	Ability to apply general rules to specific problems to come up with logical answers. It involves deciding if an answer make sense.

2738 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

16	Information Ordering	Ability to follow correctly a rule or set of rules to arrange things or actions in a certain order. The rule or sets of rules used must be given. The things or actions to be put in order can include numbers, letters, words, pictures, procedures, sentences, and mathematical or logical operations.
17	Mathematical Reasoning	Ability to understand and organize a problem and then to select a mathematical method or formula to solve the problem. It encompasses reasoning through mathematical problems to determine appropriate operations that can be performed to solve problems. It also includes the understanding or structuring of mathematical problems. The actual manipulation of numbers is not included in this ability.
18	Number Facility	Involves the degree to which adding, subtracting, multiplying, and dividing can be done quickly and correctly. These can be steps in other operations, such as finding percentages and taking square roots.
19	Time-Sharing	Ability to shift back and forth between two or more sources of information.
20	Speed of Closure	Involves the degree to which different pieces of information can be combined and organized into one meaningful pattern quickly. It is not known beforehand what the pattern will be. The material may be visual or auditory.
21	Perceptual Speed	Involves the degree to which one can compare letters, numbers, objects, pictures or patterns, quickly and accurately. The things to be compared may be pictures or patterns, quickly and accurately. The things to be compared may be presented at the same time or one after the other. This ability also includes comparing a presented object with a remembered object.
22	Reaction Time	Ability to give one fast response to one signal (sound, light, picture) when it appears. This ability is concerned with the speed with which the movement can be started with the hand, foot or other parts of the body.
23	Choice Reaction Time	Ability to choose between two or more movements quickly and accurately when two or more different signals (lights, sounds, pictures) are given. The ability is concerned with the speed with which the right response can be started with the hand, foot or other parts of the body.
24	Near Vision	Capacity to see close environmental surroundings.
25	Far Vision	Capacity to see distant environmental surroundings.
26	Night Vision	Ability to see under low light conditions.
27	Visual Color Discrimination	Capacity to match or discriminate between colors. This capacity also includes detecting differences in color purity (saturation) and brightness (brilliance).
28	Peripheral Vision	Ability to perceive objects or movements towards the edges of the visual field.
29	Depth Perception	Ability to distinguish which of several objects is more distant from or nearer to the observer or to judge the distance of an object from the observer.
30	Glare Sensitivity	Ability to see objects in the presence of glare or bright ambient lighting.
31	General Hearing	Ability to detect and to discriminate among sounds that vary over broad ranges of pitch and/or loudness.
32	Auditory Attention	Ability to focus on a single source of auditory information in the presence of other distracting and irrelevant auditory stimuli.
33	Sound Localization	Ability to identify the direction from which an auditory stimulus originated relative to the observer.

2739 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

34	Control Precision	Ability to move controls of a machine or vehicle. This involves the degree to which these controls can be moved quickly and repeatedly to exact positions.
35	Rate Control	Ability to adjust an equipment control in response to changes in the speed and/or directions of a continuously moving object or scene. The ability involves timing these adjustments in anticipating these changes. This ability does not extend to situations in which both the speed and direction of the object are perfectly predictable.
36	Wrist-Finger Speed	Ability to make fast, simple repeated movements of the fingers, hands and wrists. It involves little, if any, accuracy or eye-hand coordination.
37	Finger Dexterity	Ability to make skillful coordinated movements of the fingers of one or both hands and to grasp, place or move small objects. This ability involves the degree to which these finger movements can be carried out quickly.
38	Manual Dexterity	Ability to make skillful coordinated movements of one hand, a hand together with its arm, or two hands to grasp, place, move or assemble objects, such as hand tools or blocks. This ability involves the degree to which these arm-hand movements can be carried out quickly. It does not involve moving machine or equipment controls, such as levers.
39	Arm-Hand Steadiness	Ability to keep the hand or arm steady. It includes steadiness while making an arm movement as well as while holding the arm and hand in one position. This ability does not involve strength or speed.
40	Multi-Limb Coordination	Ability to coordinate movements of two or more limbs (for example, two arms, two legs or one leg and one arm), such as in moving equipment controls. Two or more limbs are in motion while the individual is sitting, standing or lying down.
41	Extent Flexibility	Ability to bend, stretch, twist, or reach out with the body, arms or legs.
42	Dynamic Flexibility	Ability to bend, stretch, twist, or reach out with the body, arms and/or legs, both quickly and repeatedly.
43	Speed of Limb Movement	Involves the speed with which a single movement of the arms or legs can be made. This ability does not include accuracy, careful control or coordination of movement.
44	Gross Body Equilibrium	Ability to keep or regain one's body balance or stay upright when in an unstable position. This ability includes maintaining one's balance when changing direction while moving or standing motionlessly.
45	Gross Body Coordination	Ability to coordinate the movement of the arms, legs and torso together in activities in which the whole body is in motion.
46	Static Strength	Ability to use muscle force in order to lift, push, pull or carry objects. It is the maximum force that one can exert for a brief period of time.
47	Explosive Strength	Ability to use short bursts of muscle force to propel oneself or an object. It requires gathering energy for bursts of muscle effort over a very short time period.
48	Dynamic Strength	Ability of the muscles to exert force repeatedly or continuously over a long time period. This is the ability to support, hold up or move the body's own weight and/or objects repeatedly over time. It represents muscular endurance and emphasizes the resistance of the muscles to fatigue.

2740 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

49	Trunk Strength	Involves the degree to which one's stomach and lower back muscles can support part of the body repeatedly or continuously over time. The ability involves the degree to which these trunk muscles do not fatigue when they are put under such repeated or continuous strain.
50	Stamina	Ability of the lungs and circulatory systems of the body to perform efficiently over long time periods. This is the ability to exert oneself physically without getting out of breath.

Table 6. Attribute list from Warner & Knapp, 2000.

	Attribute Name	Description
	Abilities	
1	Oral Comprehension	Ability to understand spoken English words and sentences.
2	Written Comprehension	Ability to understand written sentences and paragraphs.
3	Oral Expression	Ability to use English words or sentences in speaking so others will understand.
4	Written Expression	Ability to use English words or sentences in writing so others will understand.
5	Memorization	Ability to remember information, such as words, numbers, pictures, and procedures. Pieces of information can be remembered by themselves or with other pieces of information.
6	Problem Sensitivity	Ability to tell when something is wrong or is likely to go wrong. It includes being able to identify the whole problem as well as the elements of the problem.
7	Originality	Ability to produce unusual or clever ideas about a given topic or situation. It is the ability to invent creative solutions to problems or to develop new procedures to situations in which standard operating procedures do not apply.
8	Fluency of Ideas	Ability to produce a number of ideas about a given topic.
9	Flexibility of Closure	Ability to identify or detect a known pattern (such as a figure, word, or object) that is hidden in other material. The task is to pick out the disguised pattern.
10	Selective Attention	Ability to concentrate on a task one is doing. This ability involves concentrating while performing a boring task and not being distracted.
11	Spatial Orientation	Ability to tell where you are in relation to the location of some object or to tell where the object is in relation to you.
12	Visualization	Ability to imagine how something will look when it is moved around or when its parts are moved or rearranged. It requires the forming of mental images of how patterns or objects would look after certain changes, such as unfolding or rotation. One has to predict how an object, set of objects or pattern will appear after the changes are carried out.
13	Inductive Reasoning	Ability to combine separate pieces of information, or specific answers to problems, to form general rules or conclusions.

2741 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

14	Category Flexibility	Ability to produce many rules so that each rule tells how to group a set of things in a different way. Each different group must contain at least two things from the original set of things.
15	Deductive Reasoning	Ability to apply general rules to specific problems to come up with logical answers. It involves deciding if an answer make sense.
16	Information Ordering	Ability to follow correctly a rule or set of rules to arrange things or actions in a certain order. The rule or sets of rules used must be given. The things or actions to be put in order can include numbers, letters, words, pictures, procedures, sentences, and mathematical or logical operations.
17	Mathematical Reasoning	Ability to understand and organize a problem and then to select a mathematical method or formula to solve the problem. It encompasses reasoning through mathematical problems to determine appropriate operations that can be performed to solve problems. Table 7. Attribute list from Phillips et al., 2003.

	Attribute Name	Description
	Skills	
1	Mental reversals/rotation	Manikin test performance
2	Eye-hand coordination	Horizontal Tracking (HT) Test performance
3	Selective auditory attention	Dichotic Listening Test (DLT) performance
4	Multitasking (psychomotor + visual)	Psychomotor Test (PMT) performance

Table 8. Attribute list from Bruskiewicz et al., 2007.

	Attribute Name	Description
	Knowledge	
1	Unit/Command Objectives	Unit's function and operations; METL, mission briefs and commander's intent
2	Aviation Principals	Fundamentals of flight; force; gravity; speed; velocity; distance; motion; altitude, direction; object rotation; geography/terrain
3	Basic Operation Procedures	Loading/unloading procedures for internal and external load operation; emergency procedures; safety procedures; post-flight checks
4	Unmanned Aerial System Operations	Navigation; sensors; weapons
5	Communication Procedures	Radio, data, intercom operation; system display indicator operation; tactical report transmission; crew coordination
6	Threat Categories and Indicators	Types of enemy systems; warning and detection systems; identification
7	Reconnaissance Procedures	Scanning assigned sectors; aerial observation; route, zone, and area reconnaissance
8	Engagement Procedures	Weapons control measures; firing position operations; weapons initialization; weapon system operation; masking and unmasking; target handover procedures
9	Meteorology	Ambient light; clouds and precipitation; forces and winds; air masses and fronts; weather forecasting; storms; effects of weather on aircraft operations
10	Aeronautical Terminology	Principles and practices of navigation; aviation phraseology; standard crew terminology

2745 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

11	Operational Terms and Graphics	Chart and map reading, topography, symbology
12	Flight Rules and Regulations	Civil, military, and unit specific regulations (SOP)
	Skills	
13	Operation and Maneuvering of Unmanned Aircraft Systems	Adjusting altitude; maintaining airspeed; changing flight direction; flight control precision; recognition of flight parameters
14	Operation of Communication Systems and Equipment	Radio/aircraft systems; intercom communication systems; digital communications systems
15	Operation of Navigation Systems and Equipment	Electronic systems; navigation radio; homing; etc.
16	Operation of Sensor/Tracking Systems and Equipment	Lasers, illuminators
17	Operation of Weapon Systems and Equipment	Hellfire missile system; stinger system
18	Performance of Unmanned Aircraft Systems Operational Checks	Security checks; engine checks; run-up and taxi checks; preflight checks; after-takeoff checks; inflight checks; post-launch checks
	Abilities	
19	Management of Stressors	Recognize and cope with stress in self and others
20	Situational Awareness	Accurately perceive self, others, and aircraft in relation to the environment
21	Psychomotor Ability: Control Precision	Make highly controlled and precise adjustments in moving controls of an aircraft precisely and repeatedly
22	Psychomotor Ability: Multi-limb Coordination	Coordinate movements of two or more limbs at once (e.g., two arms, one leg and one arm)
23	Psychomotor Ability: Simple Reaction Time	Give a fast response to a signal when it appears
24	Psychomotor Ability: Choice Reaction Time	Choose between two or more movements quickly and correctly when there is more than one choice
25	Psychomotor Ability: Rate Control	Adjust an equipment control in response to changes in the speed or direction of a continuously moving object or scene, (e.g., keeping aircraft at a given altitude in turbulent weather or tracking a moving target)

2746 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

26	Perceptual Speed and Accuracy	Perceive and process visual information quickly and accurately; to notice subtle visual details
27	Oral Communication	Speak in a clear, concise and persuasive manner; to give clear directions and information; to ask questions to clarify and ensure understanding
28	Oral Comprehension	Listen to and understand information and ideas that are presented orally
29	Written Communication	Write in a logical, well-organized manner; to use correct punctuation and grammar
30	Reading Comprehension	Perceive and understand principles governing the use of verbal concepts and symbols; to interpret meaning from written information
31	Mathematical Ability	Understand and apply basic (e.g., addition, rounding) and advanced (e.g., algebra) math principles; arithmetic reasoning
32	Mechanical Comprehension	Perceive physical relationships and practical problems in mechanics; to understand the operation of mechanical equipment
33	Analytical Ability	Reason logically and critically to draw correct, well-supported, and consistent conclusions
34	Planning	Develop courses of action to accomplish objectives and avoid potential problems; to manage activities effectively; to actively prepare for high workload/problem situations
35	Organization/Time Management	Prioritize activities and determine which ones require immediate attention; to manage and allocate time effectively
36	Judgment/Decision-Making/Problem Solving	Make high quality and timely decisions; to assess the level of risk associated with a given course of action; to recognize when additional information is required to make a decision or solve a problem; to identify potential and/or novel solutions to problems; to anticipate the consequences of decisions
37	Spatial Visualization and Orientation	Recognize and distinguish shapes and patterns; to identify an object at different angles; to anticipate a moving object's spatial orientation over time; to recognize one's own physical orientation in an unfamiliar environment; to estimate location after traveling for a period of time; to read a map and understand it's content
38	Information Processing Ability: Divided Attention	Pay attention to multiple tasks occurring at the same time
39	Information Processing Ability: Selective/Focused Attention	Focus on and process information related to a single task amid the presence of competing information or background noise
40	Information Processing Ability: Working Memory	Temporarily hold information in memory, use it while performing ongoing tasks, and update it continually to reflect the current situation
41	Information Processing Ability: Long-Term Memory	Remember information for long periods of time; to recall information that was learned some time ago
42	Vigilance	Stay alert and be attentive to one's surroundings over long periods of time, including small details; to recognize hazards and threats within one's environment; to perform repetitive tasks effectively

2747 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

43	Cognitive Task Prioritization	Properly pay attention to tasks in order to achieve subgoals which support the overall mission goal; that is, ensure the Operator is "doing what he or she should be doing at all times"
	Other Characteristics	
44	Assertiveness	Tendency to act in an appropriately bold and energetic fashion in order to accomplish objectives; willingness to communicate appropriate urgency when delivering information
45	Followership	Tendency to follow requests or orders; to accept suggestions and guidance from other crewmembers without being defensive
46	Self-Regulation	Tendency to keep oneself focused on a task/work even when external factors make it difficult to do so.
47	Excitement-Seeking	Tendency to crave excitement and stimulation, but not to the point of being reckless
48	Risk-Tolerance	Willingness to accept risk and engage in activities that involve a lack of certainty or fear of failure, but without being reckless
49	Work Ethic	Tendency to strive for competence in one's work; willingness to work long hours when appropriate; tendency to reliably complete one's work in a timely fashion and complete the mission
50	Initiative	Tendency to take personal initiative in accomplishing tasks and to see tasks through until their completion
51	Self-Confidence	Being sure of one's abilities without being over-confident or arrogant
52	Straightforwardness	Tendency to be frank, sincere, and genuine
53	Helpfulness	Tendency to have an active concern for others' welfare; expressed through generosity, consideration of others, and a willingness to assist others in need of help
54	Teamwork	Tendency to function effectively as part of a team; to cooperate with other crewmembers to accomplish goals and solve problems
55	Interpersonal Skills	Tendency to understand and deal effectively with a variety of people; to treat others with courtesy and respect; to be considerate of others' needs
56	Dutifulness	Tendency to adhere to one's set of ethical principals and to strictly follow rules and regulations
57	Achievement Striving	Tendency to set ambitious goals for oneself and to work hard to attain a high level of work proficiency
58	Self Discipline	Tendency to control one's conduct and impulses
59	Deliberation	Tendency to think carefully before acting, time permitting
60	Dependability	Tendency to be reliable, planful, well-organized, disciplined, and determined
61	Responsibility	Tendency to assume responsibility and accept consequences of own decisions and actions
62	Perseverance	Tendency to stick with a task until completion in spite of obstacles
63	Integrity	Tendency to behave in a moral or ethical manner
64	Loyalty	Tendency to remain loyal to one's country, unit, superiors, peers, and subordinates
65	Stress Tolerance	Tendency to maintain composure in challenging and threatening situations
66	Adaptability/Flexibility	Tendency to adjust easily to changing situations or conditions; to quickly adapt and change priorities when needed

2748 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

67	Learning Orientation	Tendency to seek out and acquire new knowledge; natural curiosity about how things function in one's environment
68	Control	Belief that one has high levels of control over what happens in one's life and the rewards and punishments one receives
69	Resourcefulness	Tendency to use one's resources both creatively and effectively to accomplish tasks
70	Leadership: Delegation	Preference for assigning tasks and giving orders to others
71	Leadership: Performance Management	Monitor crewmember performance and take action when performance is substandard
72	Leadership: Provide Feedback	Provide performance feedback and coaching to crewmembers as necessary; able to effectively inform crewmembers of mistakes or potential problems
73	Leadership: Motivation	Motivate crewmembers to perform effectively under difficult circumstances
74	Leadership: Resolving Conflicts	Resolve conflict among crewmembers; to foster an environment of teamwork and camaraderie
75	Attention to Detail	Tendency to keep track of details; to notice even subtle changes or inconsistencies in a person or situation
76	Work in Confined Spaces	Tolerate small/confined spaces for long periods of time
77	Physical Conditioning	Tendency to be active and participate in sports, exercise and physical activity.

2749 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 9. Attribute list from Chappelle et al., 2010.

	Attribute Name	Description
	Abilities	
2	Stamina (2)	Physical stamina for sitting and sustaining vigilance for extended periods. Postural strength & endurance. Resilience to physical and cognitive fatigue.
3	Cognitive Proficiency	General cognitive ability. Speed and accuracy of information processing.
4	Visual Perception	Visual acuity, scanning and discrimination. Visual recognition, tracking and analysis.
5	Attention	Vigilance to multiple sources of visual & auditory information (situational awareness). Sustained and divided attention to visual and auditory information.
6	Spatial Processing	Spatial analysis and orientation. Spatial reasoning and construction (manipulation of 2-diminesional information into 4-dimensional mental imagery).
7	Memory	Visual and auditory memory (working, immediate, and delayed). Spatial memory (working, short-term, and delayed).
8	Reasoning	Real time general and deductive reasoning (problem solving). Carefully and quickly assess risk, likely outcomes, and potential repercussions (forward thinking). Quickly perceives the next steps and multi·tasks high level of information and procedures (task prioritization and management).
	Other Characteristics	
1	General Health	No significant or chronic injuries, illnesses, or defects affecting performance (e.g., manual dexterity, vision, posture) or reliability. Resilience to shift work adjustments.
9	Composure	Remains composed and in control of behavior and emotions under stress. Effectively compartmentalizes emotions.
10	Resilience	Emotional stamina and hardiness in response to monotony, confined workspace, and high pressure situations.
11	Self-Certainty	Clear sense of self-confidence. Clear sense of role as war-fighter. Maintains confidence during performance feedback.
12	Conscientiousness	Deliberate, methodical, and organized. Self disciplined.
13	Success Oriented	Self-motivated and driven to succeed. Committed to self-improvement.
14	Perseverance	Sustains a high level of effort over long periods of time despite hardships.
15	Decisiveness	"Real time" decision making during monotony and high pressure situations.
16	Humility	Effectively recognizes the need and asks for help. Seeks and accepts performance feedback from others.
17	Cohesiveness	Values the role and supportive of other personnel. Participates in morale building exchanges.
18	Assertiveness	Speaks up and effectively voices concerns in "real time." Provides appropriate and decisive feedback.
19	Adaptability	Generally flexible, realistic, and effectively responds to change and unpredictable stressors.

2750 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

20	Moral Interest	Motivated to save lives and protect U.S. and coalition forces. Personal beliefs and world views (spiritual, religious) support combat operations.
21	Occupational interest	Possess a sense of duty as a war fighter. Realistically understands and intrinsically appreciates RPA platform. Critical to retention: Enjoys duties of the position and contribution to daily operations in theater, strong intrinsic interest in advanced and emerging avionic RPA technology. Strong interest in advancing national interests and mission objectives.

Table 10. Attribute list from Chappelle et al., 2011.

	Attribute Name	Description
	Abilities	
1	Cognitive Proficiency	General cognitive ability. Speed & accuracy of information processing.
2	Visual Perception	Visual acuity, scanning and discrimination. Visual recognition, tracking and analysis.
3	Attention	Vigilance to multiple sources of visual and auditory information (situational awareness). Sustained and divided attention to visual and auditory information.
4	Spatial Processing	Spatial analysis and orientation. Spatial reasoning and construction (manipulation of 2-diminesional information into 4-dimensional mental imagery).
5	Memory	Visual and auditory memory (working, immediate, and delayed). Spatial memory (working, short-term, and delayed).
6	Reasoning	Real time general and deductive reasoning (problem solving). Task prioritization. Carefully and quickly assess risk, likely outcomes, and potential repercussions (forward thinking). Cognitive flexibility (thinking outside the box).
7	Psychomotor Processing	Fine motor dexterity and reaction time. Psychomotor-spatial coordination and accuracy.
	Other Characteristics	
8	Emotional Composure	Remains calm, composed, and in control of behavior and emotions under stress (e.g., does not readily show or experience fear, sadness, or irritability).
9	Resilience	Emotional stamina and hardiness in response to monotony, confined workspace, and high pressure situations.
10	Self-Certainty	Clear sense of self-confidence across routine and high pressure tasks and situations. Clear sense of role as an officer and war-fighter.
11	Conscientiousness	Deliberate, methodical, and highly organized. Highly dependable, reliable and self disciplined.
12	Perseverance	Completes tasks despite boredom, hardship, and potential distractions. Sustains a high level of effort over long periods of time despite hardships.
13	Success Oriented	Self-motivated and driven to succeed and achieve . Seeks new and innovative ways to improve performance. Strong interest in mastering challenging tasks and in emerging computer-based technology.
14	Decisiveness	Makes decisions in real time, under pressure, and within operational deadlines. Operationally patient in making the right decision and committing to a course of action.
15	Adaptability	Effectively sizes up and deals with problematic situations and environmental demands. Generally flexible, realistic, and effectively understands problematic stressors in occupational and personal settings. Finds good ways of managing and resolving stressors and conflicts. Effective compartmentalization of personal stress from occupational duties.
16	Humility	Ability to recognize the need and willingness to seek help from leadership and others.

2752 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

17	Extraversion	Open and accepting of critical feedback from peers, subordinates and others. Shares credit for success, accepts responsibility for mistakes. Receptive and approachable. Socially engaging and outgoing; fosters positive relations. Understands and effectively responds to emotional states of others.
18	Judgment	Comfortable with different personality styles and working under constrained and varied conditions. Situationally aware; responsive; effectively resolves/diffuses interpersonal conflict. Social behavior at work and off-base settings demonstrates prudence for national security and the integrity of military operations.
19	Team Oriented	Comfortable leading, working with enlisted personnel as a team. Competitive disposition but does not jeopardize group and mission goals for individual goals. Interest in teaching others and promoting morale. Trusting of other aircrew and military personnel.
20	Moral	Motivated to save lives and protect U.S. and coalition forces. Personal beliefs and world views (spiritual, religious) support combat operations.
21	Occupational	Possesses a sense of duty as an officer and warfighter. Realistically understands and appreciates RPA platform. Strong interest in advanced and emerging avionic RPA technology. Enjoys duties of the position and contributes to daily operations in theater. Strong interest in advancing national interests and mission objectives.

A simple means of comparing attributes across studies is presented in Table 11. This table lists all of the identified KSAOs that were used in one way or another, for example in the construction of a selection battery. As a result, for example, the Knowledge and Skills identified in Bruskiewicz et al. are not listed here because they were excluded from construction of the selection battery on the grounds that the Knowledge and Skills identified would be imparted in the training process. The left most column in Table 11 lists the unique attribute names from all of the studies reviewed here. In the columns to the right are the attribute numbers of the study named in their headers. With the exception of the second column, which lists the attribute numbers from Fleishman and Qaintance (1984), the attribute lists are not in numeric order. The numbers have been placed in the row that best corresponds, according to compared definitions, to the attribute name in the left column. Attribute numbers may appear in more than one row because of overlapping definitions or lack of specificity, in more than one row. Therefore Table 11 is a cross reference of KSAOs identified and used among the studies reviewed in this report.

Future KSAOs

Of the reports reviewed above there are three that identified KSAOs with an intent to anticipate future requirements. The first two, Barnes et al. (2000) and Warner et al. (2000), were not aimed at development of personnel selection instruments, but rather design considerations for future systems and their impact on manpower requirements. The first issue for consideration in Barnes et al. concerned the need for rated aviators as operators rather than enlisted personnel. The authors did not find evidence to support the replacement of enlisted personnel in either the AVO or EP positions with rated aviators. They instead pointed to training solutions as the best alternative for addressing the demands of expected design changes. Additionally, the authors found no evidence to compel the introduction of image or intelligence analysts into the RPA crew complement. They did conclude that some of the skills possessed by image and intelligence analysts could have application within the RPA crew for certain missions. Again, their recommended solution was to approach this through training.

Warner and Knapp (2000) were concerned with the impact of an enhanced CGS, then in development, on manpower and personnel requirements. Most, but not all, of the features of that

2756 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

developmental system have been implemented. The authors predicted a skill shift toward increased demand for analytical skills (and presumably the abilities that enable those skills) in the enhanced CGS. Much of that shift was expected to stem from increased reliance on and intelligence and imagery analysis by the RPA crew. As in the previous study, the authors concluded that the introduction of imagery and intelligence analysts into the RPA crew would not be cost effective and that it would be more practical to augment training for Army RPA operators to impart the needed skills. The recommendations of both of these studies regarding training solutions have been partly implemented and are continuing. However, there is a long road ahead, at least for the Army, in implementing sufficient training enhancements to cover the needs of future systems.

Government guidance at the outset of the project that produced the Bruskiewicz et al. (2007) report was specific in the need to consider the likely impact of near future changes on personal attribute demands that could affect personnel selection criteria. To address this, the authors included a sample of SMEs who had special knowledge of developments in the RPA arena in their administration of the JAQ. These SMEs were requested to apply their knowledge of coming changes to their ratings. This approach appears to have had an effect because the SME subgroup produced somewhat different ratings, as illustrated in the review above.

The emphasis in these three examples of anticipation of shifts in operator KSAO demand is on design changes to the RPA systems. These changes were expected both in the user interface (CGS) and in expanded system capabilities (e.g. weaponization). System design changes constitute only one of several sources that can drive shifts in KSAO demand. Other drivers include changes in organization, manpower and missions.

Addition of new system capabilities or expansion of existing system capabilities most often increase total demand while differentially affecting demand across attribute domains. Even "improved" designs can be a double edged sword. The control interface and display systems for RPA operation are getting improvements that are intended to reduce total workload and reduce demand on perceptual-motor abilities, but as workload decreases it is common to see an increase in expectations that translate into expanded mission requirements or addition of still more new capabilities. Likewise, increases in automation are often viewed as opportunities to add new requirements. Another area within system capabilities is the continued weaponization of RPA systems. Introduction of an onboard munition adds far more than the requirement for knowledge and skills relevant to operation of that subsystem. It also adds intellectual and decision making requirements related to knowledge and interpretation of the current rules of engagement, commander's intent for the current mission, and understanding of the performance envelope and constraints of the weapon and its terminal effects (e.g., burst radius). Attitudinal and personality attributes that previously were not particularly prominent may take on much greater importance when the system that a person is operating becomes deadly. The addition of weapons also changes the system's area and timeline of influence in a mission. Even if the decision to employ a weapon is made outside the CGS, the crew inside are faced with another set of decision points that have a characteristic of immediacy. Therefore the personal attributes that mediate decision speed will be in greater demand.

There also has been, over the past decade, increasing effort expended toward development of the capability for a RPA crew to control multiple RPAs simultaneously. Beyond the obvious impact on total workload, this capability places increased demand for KSAOs that mediate situation

2757 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

awareness. With multiple airframes under their control, AVOs and MPOs need greater application of selective and divided attention, spatial orientation, and time sharing.

Changes in organization can have both direct and indirect effects on KSAO demand. The recent transfer of Army UAS assets and responsibility from the Military Intelligence (MI) Branch to the Aviation Branch (AVN) is having a large effect on attribute demands for UAS operators. Under MI, UAS missions, and therefore training (especially on-the-job training), concentrated on intelligence, surveillance, and reconnaissance (ISR). Under AVN there is a transition to a much broader scope that parallels manned aviation assets. This includes not only reconnaissance, surveillance, and target acquisition (RSTA), but also command, control, communications and intelligence (C3I) as well as other roles and functions. This transition has been shown (Stewart, Bink, Barker, Tremlett, & Price, 2011) to have resulted in gaps in training that are slowly being addressed. Rectification, through augmented training content, in itself will increase demand for cognitive abilities. In addition, the transition involves increased requirements for RPA operators to interact with personnel outside their immediate (RPA) community.

The Air Force is beginning to confront a major change in manpower relevant to RPA systems. The transition from requiring RPA pilots first be qualified manned aircraft pilots to personnel who have only completed the Undergraduate Remotely Piloted Aircraft Training (URT) course with much less hands-on flying training is a step that may produce shifts in the experiential background and attitudes of the RPA pilot population. Changes in the general population from which all RPA operators are ultimately obtained can also alter the complement of abilities and other attributes of people available for entry into RPA crew positions.

Changes in RPA missions can result from changes in organization and/or system capabilities, as well as other causes. In recent years the scope of RPA missions has greatly increased to include a far broader range of reconnaissance and targeting, and is now moving into the attack realm. This increase in mission scope has consequences in communications, cognitive abilities, and other attributes such as time-sharing and teamwork. A major increase in mission scope is the expanding use of manned-unmanned arial teaming (MUM). In MUM missions a RPA is teamed with one or more manned aircraft (e.g. OH-58D Kiowa Warrior) to carry out reconnaissance/ attack operations. This requires close interaction between the system crews, as well as with supporting and commanding ground units. As a result, RPA crews and manned aircraft crews must acquire knowledge of each others system capabilities and limitations and develop a common lexicon for efficient communications. In addition, demand for time-sharing and situational awareness are increased because of the need to maintain awareness of the status of every system in the team. Recently, Pavlas et al. (2009) analyzed the features of MUM teaming to identify knowledge, skills, and attitudes that are demanded by these missions and will require augmented training. They identified a combined 60 areas that acquire increased demand in MUM operations. While their focus is on training solutions, their findings should be reviewed to determine where the training burden could be mitigated by shifts in KSAOs used for selection.

Table 12 presents the KSAO list from Table 11 and expresseses expected shifts in demand based on consideration of the factors outlined above. A "+" indicates an expected increase in demand, a "–" indicates an expected decrease. A "0" indicates no expected change and an "X" indicates the attribute is not well enough defined to be evaluated, and should be dropped.

Conclusion

There are very few published treatments of KSAOs for RPA operators and most of those have severe methodological deficiencies. Of those reviewed here only three (Barnes et al., 2000; Bruskiewicz et al., 2007; Warner & Knapp, 2000) could be considered rigorous and systematic in their approach. There appear to be no instances of RPA operator selection instruments that have been validated. The closest to that would be the battery developed by Bruskiewicz, et al, which could be implemented for validation in a short time. Services should, however, conduct studies of training failure rates to determine if the costs of development and fielding selection instruments are justifiable.

The demand for specific abilities and other attributes in persons entering training as RPA operators is driven by changes occurring in system capabilities, organization, manpower, and missions. Overall, the positions within RPA crew are acquiring an increased demand although some attributes are likely to see decreases. These changes are likely to have an even greater impact on training requirements.

The area of RPA KSAOs is prone to confusion stemming from differences in terminology regarding operational systems and their names, and names and definitions of crew positions. Greater confusion stems from conflicting definitions of personal attributes, loosely defined attributes and a proliferation of ad hoc attributes with little or no theoretical basis. There is a critical need for a KSAO taxonomy that minimizes overlap between attributes and covers the range of behaviors critical to system operation.

EXECUTIVE SUMMARY

U.S. and allied combat operations continue to highlight the value of unmanned systems in the modern combat environment. Combatant Commanders (CCDRs) and warfighters value the inherent features of unmanned systems, especially their persistence, versatility, and reduced risk to human life. The U.S. military Services are fielding these systems in rapidly increasing numbers across all domains: air, ground, and maritime. Unmanned systems provide diverse capabilities to the joint commander to conduct operations across the range of military operations: environmental sensing and battlespace awareness; chemical, biological, radiological, and nuclear (CBRN) detection; counter-improvised explosive device (C-IED) capabilities; port security; precision targeting; and precision strike. Furthermore, the capabilities provided by these unmanned systems continue to expand.

The Department of Defense (DoD) has been successful in rapidly developing and fielding unmanned systems. DoD will continue to focus on responding rapidly to CCDR requirements, while ensuring systems are acquired within the framework of DoD's new wide-ranging Efficiencies Initiatives[1]. In the fiscal environment facing the Nation, DoD, in concert with industry, must pursue investments and business practices that drive down life-cycle costs for unmanned systems. Affordability will be treated as a key performance parameter (KPP) equal to, if not more important than, schedule and technical performance. DoD will partner with industry to continue to invest in unmanned systems technologies while providing incentives for industry to implement cost-saving measures and rewarding industry members that routinely demonstrate exemplary performance.

> My Acquisition Decision Memorandum (ADM) approving formal program commencement of the program will contain an affordability target to be treated by the Program Manager like a Key Performance Parameter (KPP) such as speed, power, or data rate ….
>
> *–Under Secretary of Defense Memorandum for Acquisition Professionals, Better Buying Power, September 2010*[1]

This document provides a DoD vision for the continuing development, fielding, and employment of unmanned systems technologies. Since publication of the last DoD Roadmap in 2009, the military Services have released individual Service roadmaps or related strategy documents. This roadmap defines a common vision, establishes the current state of unmanned systems in today's force, and outlines a strategy for the common challenges that must be addressed to achieve the shared vision.

The challenges facing all military Services in the Department include:

1) Interoperability: To achieve the full potential of unmanned systems, these systems must operate seamlessly across the domains of air, ground, and maritime and also operate

[1] Better Buying Power, Guidance for Obtaining Greater Efficiency and Productivity in Defense Spending, OUSD(AT&L) Memo, Dr. Ashton B. Carter, 14 September 2010.

2769 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

seamlessly with manned systems. Robust implementation of interoperability tenets will contribute to this goal while also offering the potential for significant life-cycle cost savings.

2) Autonomy: Today's iteration of unmanned systems involves a high degree of human interaction. DoD must continue to pursue technologies and policies that introduce a higher degree of autonomy to reduce the manpower burden and reliance on full-time high-speed communications links while also reducing decision loop cycle time. The introduction of increased unmanned system autonomy must be mindful of affordability, operational utilities, technological developments, policy, public opinion, and their associated constraints.

3) Airspace Integration (AI): DoD must continue to work with the Federal Aviation Administration (FAA) to ensure unmanned aircraft systems (UAS) have routine access to the appropriate airspace needed within the National Airspace System (NAS) to meet training and operations requirements. Similar efforts must be leveraged for usage of international airspace.

4) Communications: Unmanned systems rely on communications for command and control (C2) and dissemination of information. DoD must continue to address frequency and bandwidth availability, link security, link ranges, and network infrastructure to ensure availability for operational/mission support of unmanned systems. Planning and budgeting for UAS Operations must take into account realistic assessments of projected SATCOM bandwidth, and the community must move toward onboard pre-processing to pass only critical information.

5) Training: An overall DoD strategy is needed to ensure continuation and Joint training requirements are in place against which training capabilities can be assessed. Such a strategy will improve basing decisions, training standardization, and has the potential to promote common courses resulting in improved training effectiveness and efficiency.

6) Propulsion and Power: The rapid development and deployment of unmanned systems has resulted in a corresponding increased demand for more efficient and logistically supportable sources for propulsion and power. In addition to improving system effectiveness, these improvements have the potential to significantly reduce life-cycle costs.

7) Manned-Unmanned (MUM) Teaming: Today's force includes a diverse mix of manned and unmanned systems. To achieve the full potential of unmanned systems, DoD must continue to implement technologies and evolve tactics, techniques and procedures (TTP) that improve the teaming of unmanned systems with the manned force.

This Roadmap leverages individual Service roadmaps and visions, and identifies challenges that might stand in the way of maturing those visions to a shared Joint vision. The vignettes provided at the beginning of the Roadmap give the reader a glimpse into potential unmanned systems capabilities. They do not serve as requirements—the individual Services will continue to identify requirements gaps and utilize the Joint Capabilities Integration and Development System (JCIDS) to determine which requirements to fund. The chapters that follow the vignettes identify core areas that are challenges for further growth in unmanned systems and chart out science, technology, and policy paths that will enable unmanned systems to fulfill an expanding role in

2770 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

supporting the warfighter. Success in each of these areas is critical to achieve DoD's shared vision and realize the full potential of unmanned systems at an affordable cost.

> … the ability to understand and control future costs from a program's inception is critical to achieving affordability requirements.
>

1 INTRODUCTION/SCOPE

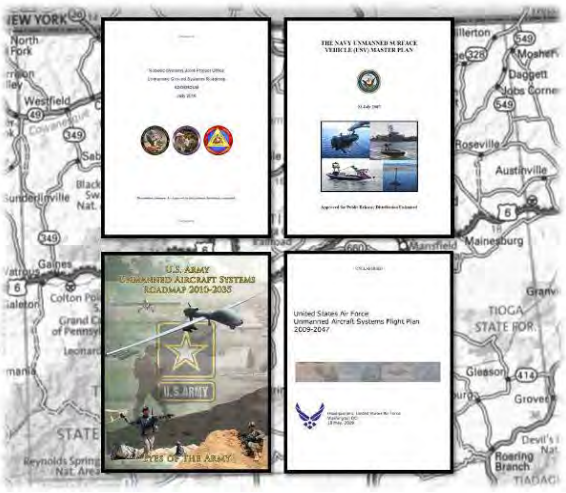
1.1 Purpose

The purpose of this document is to describe a vision for the continued integration of unmanned systems into the Department of Defense (DoD) Joint force structure and to identify steps that need to be taken to affordably execute this integration. DoD has seen rapid growth, sparked in large part by the demands of the current combat environment, in the development, procurement, and employment of unmanned systems. Today's deployed forces have seen how effective unmanned systems can be in combat operations. This experience has created expectations for expanding the roles for unmanned systems in future combat scenarios. This Roadmap establishes a vision for the next 25 years and outlines major areas where DoD and industry should focus to ensure the timely and successful adoption of unmanned systems.

1.2 Scope

This Roadmap follows the path originally laid out in the 2007 and 2009 Roadmaps in addressing all three unmanned domains: air, ground, and maritime. However, this document deviates from the earlier editions, primarily as a result of the following:

- An Unmanned Systems Roadmap survey conducted by the Office of the Under Secretary of Defense (Acquisition, Technology, and Logistics) (OUSD(AT&L))
- Publication of service-specific roadmaps for unmanned systems



Shortly after the publication of the 2009 Roadmap, OUSD(AT&L) conducted a survey of key stakeholders and users of the Roadmap. The survey sampled a wide audience, including: Office of the Secretary of Defense (OSD), Service headquarters, warfighting commands, Service acquisition organizations, Service laboratories, multiple Joint organizations, other government agencies, industry (both large and small businesses), and academia. One of the major outcomes of this survey was a decision to capture the catalog function of the Roadmap in a separate, online tool. The reason for this decision is that the online tool provides greater functionality than that of the two-dimensional, hard-copy catalog, including the capability for more frequent updates than the biennial printed Roadmap. The catalog can be found on the Unmanned Warfare Information Repository site at: **https://extranet.acq.osd.mil/uwir/**.

The survey also helped define the audience for the 2011 edition. This Roadmap provides a common vision and problem set to help shape military Service investments. The document also describes DoD's direction to help industry participants shape their investments, particularly with respect to independent research and development.

Since the publication of the 2009 Roadmap, each military Service has developed its own roadmap or equivalent document (listed in Appendix A). The U.S. Air Force (USAF) released its "Unmanned Aircraft Systems Flight Plan" in 2009 outlining an actionable plan across the diverse spectrum of doctrine, organization, training, materiel, leadership and education, personnel, facilities, and policy (DOTMLPF-P). In 2009, the U.S. Army published the "Unmanned Ground Systems Roadmap," providing a common resource document for Army and U.S. Marine Corps (USMC) stakeholders in unmanned ground vehicles (UGVs). The Army released its unmanned

2775 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

aircraft systems (UAS) Roadmap in 2010, which established a broad vision for developing, organizing, and employing UAS across the spectrum of Army operations. In November 2009, the USMC published its "Concept of Operations for USMC Unmanned Aircraft Systems Family of Systems (CONOPS for USMC UAS FoS)." Finally, the U.S. Navy published its "Information Dominance Roadmap for Unmanned Systems" in December 2010. In light of these recent publications (see right), this Roadmap was tailored to focus on common issues facing all Services as well as to articulate a vision for achieving these goals in today's fiscal environment. The goal for this document is to serve as a single, unified source to clearly articulate the DoD common vision for unmanned systems and to identify a common problem set facing DoD in maximizing the military utility offered by these versatile and innovative systems.

2776 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2 VISION

The Department of Defense's vision for unmanned systems is the seamless integration of diverse unmanned capabilities that provide flexible options for Joint Warfighters while exploiting the inherent advantages of unmanned technologies, including persistence, size, speed, maneuverability, and reduced risk to human life. DOD envisions unmanned systems seamlessly operating with manned systems while gradually reducing the degree of human control and decision making required for the unmanned portion of the force structure.

… to ensure safe, effective and supportable capabilities are provided while meeting cost, schedule and performance. The parallel vision is to provide continuous improvement of unmanned system capabilities to meet current and future Warfighter objectives.

– Mission and Vision, Robotic Systems Joint Project Office Unmanned Ground Systems Roadmap, July 2009

… develop and field cost-effective USVs to enhance Naval and Joint capability to support: Homeland Defense, the Global War on Terror, Irregular Warfare, and conventional campaigns.

– The USV vision, The Navy Unmanned Surface Vehicle Master Plan, 23 July 2007

… adopt innovative strategies to provide cost effective logistical support …

– Goals and Objectives, US Army Roadmap for UAS 2010-2035

… to harness increasingly automated, modular, globally connected, and sustainable multi-mission unmanned systems resulting in a leaner, more adaptable and efficient Air Force that maximizes our contribution to the Joint Force.

– USAF vision, USAF Unmanned Aircraft Systems Flight Plan 2009-2047

2.1 Future Operational Environment

The strategic environment and the resulting national security challenges facing the United States for the next 25 years are diverse. The United States faces a complex and uncertain security landscape in which the pace of change continues to accelerate. The rise of new powers, the growing influence of nonstate actors, the spread of weapons of mass destruction and other irregular threats, and continuing socioeconomic unrest will continue to pose profound challenges to international order.

2777 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Over the next two decades, forces will operate in a geostrategic environment of considerable uncertainty with traditional categories of conflict becoming increasingly blurred. This era will be characterized by protracted confrontation among state, nonstate, and individual actors using violent and nonviolent means to achieve their political and ideological goals. Future adversaries will rely less on conventional force-on-force conflicts to thwart U.S. actions and more on tactics that allow them to frustrate U.S. intentions without direct confrontation.

> The future operating environment will be one of constant and accelerating change. Economic, demographic, resource, climate, and other trends will engender competition locally, regionally, and globally…. State and non-state actors will find new and more deadly means of conducting operations in all domains, to include land, air, maritime, and cyberspace to further their aims … otherwise leveraging land, air, and maritime areas to ensure their freedom of movement and deny it to others..
>
> *– Joint Operational Concept, Irregular Warfare: Countering Irregular Threats*

As technological innovation and global information flows accelerate, nonstate actors will continue to gain influence and capabilities that, during the past century, remained largely the purview of states. Chemical and biological agents will become increasingly more accessible, lethal and sophisticated. Both state and nonstate actors will actively pursue nuclear weapons, sophisticated and/or bioengineered biological agents, and nontraditional chemical agents.

> The next quarter century will challenge U.S. Joint Forces with threats and opportunities ranging from regular and irregular wars in remote lands, to relief and reconstruction in crisis zones, to cooperative engagement in the global commons …. There will continue to be opponents who will try to disrupt the political stability and deny free access to the global commons that is crucial to the world's economy…. In this environment, the presence, reach, and capability of U.S. military forces, working with like-minded partners, will continue to be called upon to protect our national interests.
>
> *– Joint Operating Environment 2010: Ready For Today, Preparing For Tomorrow*

Unmanned systems can help in countering these threats by reducing risk to human life and increasing standoff from hazardous areas.

2778 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2.2 DoD's Vision

The DoD, along with industry, understands the effect that innovation and technology in unmanned systems can have on the future of warfare and the ability of the United States to adapt to an ever-changing global environment. DoD and industry are working to advance operational concepts with unmanned systems to achieve the capabilities and desired effects on missions and operations worldwide. In building a common vision, DoD's goals for unmanned systems are to enhance mission effectiveness, improve operational speed and efficiency, and affordably close warfighting gaps.

DoD is committed to harnessing the potential of unmanned systems and strengthening mission effectiveness while maintaining fiscal responsibility. DoD will also work on establishing a complementary relationship between manned and unmanned capabilities while optimizing commonality and interoperability across space, air, ground, and maritime domains.

Open architecture (OA) and open interfaces need to be leveraged to address problems with proprietary robotic system architectures. Standards and interface specifications need to be established to achieve modularity, commonality, and interchangeability across payloads, control systems, video/audio interfaces, data, and communication links. This openness will enhance competition, lower life-cycle costs, and provide warfighters with enhanced unmanned capabilities that enable commonality and joint interoperability on the battlefield.

By prudently developing, procuring, integrating, and fielding unmanned systems, DoD and industry will ensure skillful use of limited resources and access to emerging warfighting capabilities. Pursuing this approach with unmanned systems will help DOD sustain its dominant global military power and provide the tools required by national decision-makers to influence foreign and domestic activities while adapting to an ever-changing global environment. The following quotation captures the breadth of the challenge:

> I speak for the Navy, that unmanned systems have to address all of the domains in which the Navy operates…. We operate on the surface, above the surface, into space, but then we operate below the surface. So when we talk about unmanned and … as we knit all of this capability together and capacity together, it has to take into account that we're operating in all those different domains.
>
> *– Admiral Gary Roughead, Chief of Naval Operations (CNO)*

With the current fiscal environment of constrained budgets, affordability is a factor across the entire acquisition cycle and must be actively engaged by the program managers, users, trainers, and testers to identify problems early, and address cost throughout the life cycle. A dollar saved early results in hundreds of saved dollars compared to problems resolved in production or worse yet during operations and support. While "open systems architecture and data rights" are critical to keeping costs in check, emphasizing the removal of obstacles to competition and the

2779 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

opportunities in test and evaluation (T&E) to facilitate competitive analysis is equally important to reduce developmental costs.

The assembly line of activity involved in producing unmanned systems must address risk across the life cycle to address the new challenges of testing autonomous functionality in the initial stages, and evaluating the operation and support issues involved in sustainment for increasing reliability, availability, and maintainability. The emphasis on vignettes at a mission level only indirectly emphasizes the increasing need for an evolutionary capability in unmanned systems production that is resilient and responsive to the dynamic situation faced by today's warfighter. New technology, methodologies, and human resourcing are critical for establishing rapid acquisition environments that maximize the potential for unmanned systems production.

2.3 Vignettes

The following vignettes offer examples of the increased capability and flexibility inherent in unmanned systems as DoD continues to field unmanned technologies and integrate resulting systems into its existing force structure. These vignettes are not intended to present an exhaustive list of the possibilities, but rather to present a few examples to illustrate the vision described throughout this Roadmap.

2.3.1 Interoperability Across Domains Vignette, 2030s

Location: Northern Pacific Littoral Areas

Situation: The number and boldness of coordinated, provocative efforts between the Republic of Orangelandia (ROO) and the increasing number of radicalized Islamic nation-states within the tropic zones (± 20° latitude) have increased over the past 15 years. ROO has demonstrated a delivery capability for nuclear intercontinental ballistic missiles, and several radical Islamic nations now openly possess nuclear weapon technology. Although nuclear power's role is expanding, oil remains the energy resource of preference even though gaining access to oil by Western nations has become increasingly constrained and expensive. The United States' gross domestic product (GDP) is being challenged by China.

Scenario: A 50-year-old, former Soviet-era, *Akula* class, nuclear-powered attack submarine sails out of ROO's Molan harbor at night unobserved by Western reconnaissance satellites. Movements of ROO submarines are of high interest due to their rarity (fewer than a dozen occurrences a year) and primarily due to ROO's status as a rogue, nuclear-capable nation-state. The submarine's departure is detected by the underwater surveillance grid, which is monitoring vessel movements in and out of the ROO waters. Ahead of the submarine, a glider unmanned underwater vehicle (UUV) is autonomously

2780 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

detached from the local network to intercept the faster submarine. Closing to within 50 yards as the submarine passes, the UUV succeeds in attaching a tether to the submarine, which begins pulling the UUV along (see figure right). As the submarine dives below the UUV's operating depth, the UUV adjusts the tether to maintain its position close to the surface. Every three hours, it glides to the surface and transmits a low-power position report.

The position reports are received by an orbiting communications relay, Baton One, an EQ-25 UAS operating at 75,000 ft in the eastern Pacific region. The EQ-25 is an extreme-endurance UAS, capable of operating for two months on station without refueling. As the submarine enters the Sea of Okhotsk and heads toward the North Pacific Ocean, U.S. military commanders are faced with a decision. Despite the advanced battery technology of the UUV, the battery life is finite; therefore, the operators have three courses of action affecting their surveillance operation: (1) continue surveillance by shifting the orbit of Baton One to maintain reception range on the UUV, which will otherwise be lost in 12 hours (2) save the UUV by detaching it when its remaining power is still sufficient for it to recover itself (within three days) or (3) expend the UUV by keeping it attached until its power is exhausted (within six days). Because ROO submarines seldom sortie beyond the littoral seas of northeastern Asia, they decide to shift Baton One's orbit and wait to decide the UUV's fate until the submarine's intent becomes clearer.

By the third day, the submarine is heading toward the mid-Pacific and the Hawaiian Islands. Because the value of the mission exceeds the cost of the asset, the decision is made to expend the low-cost UUV to buy time for a naval anti-submarine warfare (ASW) ship to intercept and track the submarine. The following day, the submarine reverses course. Two days later, the still-attached UUV converts to beacon mode to conserve its dwindling power reserves, Baton One returns to its planned orbit, and the ASW ship turns for Pearl Harbor. A Broad Area Maritime Surveillance (BAMS) UAS, MQ-4C, is launched from Guam to track the beacon. It recovers the beacon's signal and determines that it is stationary. Autonomously descending with its internal airborne sense and avoid (ABSAA) system to maintain "due regard," the BAMS UAS is able to visually acquire the UUV, floating in mid-ocean and no longer attached to the ROO submarine — potentially detached by the submarine's crew. The submarine's position and intent are now unknown.

Ten days later, a weak seismic disturbance is detected 150 miles southeast of Anchorage, Alaska (see map below). Several minutes later, a much more significant event registers 3.5 on the Richter scale. An interagency DoD/homeland defense reconnaissance UAS is launched out of Elmendorf Air Force Base (AFB) and detects a radiation plume emanating near Montague Island at the mouth of Prince William Sound. The UAS maps the plume as it begins spreading over the sound, and a U.S. Coast Guard offshore patrol cutter deployed from Kodiak employs its

2781 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

embarked unmanned helicopter to drop buoys with chemical, biological, radiological, and nuclear (CBRN) sensors in the Sound and within narrow passes to measure fallout levels. The plume begins to spread over the sound and threatens the city of Valdez. All vessel traffic, mainly oil tankers, transiting in and out of the Sound is stopped, and operations at the oil terminal are suspended. Oil storage facilities at the terminal are quickly filled to capacity, and the flow from Prudhoe Bay is shut down. The port of Valdez, the largest indigenous source of oil for the United States, is effectively under quarantine.

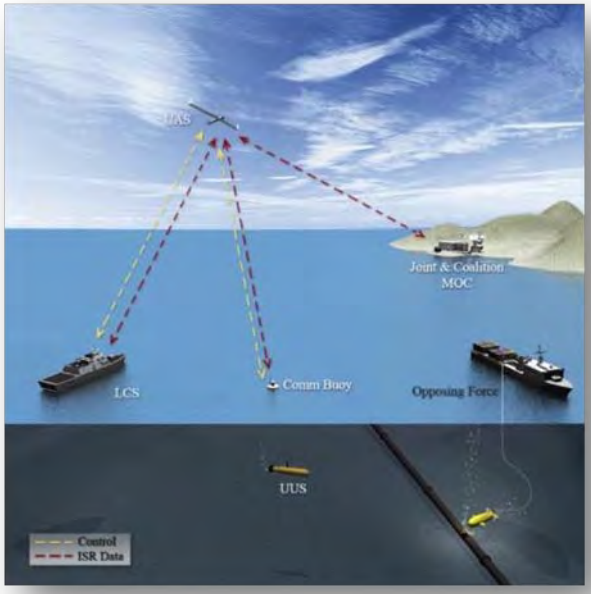
Due to the growing contamination of the local environment, disaster response officials decide to request the support of the military because of their experience both with operations in CBRN zones and with unmanned systems, which are the tools of choice because of the contamination hazards to personnel. The amphibious transport dock ship USS *New York* anchors near an entrance to Prince William Sound and begins operations with its unmanned surface vehicles (USVs) and MQ-8 detachments. An EQ-25 orbit is established over the Sound to ensure long-term, high-volume communication capability in the high-latitude, mountainous region. With data compression technology fielded in the transmitting and relay systems, the EQ-25 is capable of handling all the theater data relay requirements. A USV proceeds to the focus of contamination and lowers a tethered remotely operated vehicle (ROV) to conduct an underwater search for the source. The USV's sonar quickly locates a large object in very shallow water and, on closer inspection by the ROV, images the severely damaged hull of what appears to be an *Akula* class submarine. The hull is open to the sea, and the ROV places temperature gradient sensors on the hull and inserts gamma sensors into the exposed submarine compartments. The Joint Task Force that was formed to manage the disaster quickly determines that the reactor fuel core is exposed to the sea and that the reactor was not shut down and is still critical. Suspicion of the submarine's origin centers on its being from ROO, but all evidence that this vessel is the lost *Akula* submarine is currently circumstantial.

The radiation plume has now encompassed the evacuated town of Valdez, and MQ-8s fly repeated sorties to the town, dock, and terminal areas to deploy UGVs with sensors and collect samples for analysis. Returning USVs and MQ-8s are met and serviced by personnel in hazmat gear and washed down after each sortie. With conditions deteriorating, two unmanned Homeland Defense CBRN barges fitted with cranes, containers, and remote controls arrive from Seattle. USVs are stationed in the narrow straits leading into the Sound with hydrophones to broadcast killer whale sounds to frighten fish outside the Sound away from the contaminated area. Over the next two weeks, with the assistance of U.S and coalition ROVs equipped with cutting torches, grappling fixtures, and operating from USVs, one remotely operated submersible barge is able to work around the clock with impunity against exposure levels to recover the exposed fuel sources and to isolate them in specially designed containers. A second barge similarly retrieves sections of the crippled submarine. Both barges operate with a high degree of autonomy, limiting exposure of personnel to the radioactive contamination.

The UGVs continue monitoring contamination levels and collecting samples, but now also start conducting decontamination of the oil terminal control station and the local power and water facilities. Highly contaminated soil is placed into steel drums, and larger UGVs are used to dig pits and bury contaminated building and pipeline materials. Advanced sensor technology and control logic allows the UGVs to operate around the clock with human operators serving solely in a monitoring function. USVs are used to collect carcasses floating in the Sound and bring

2782 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

them to shore for disposal. UUVs crisscross the seafloor of the Sound to locate and tag remnants of the submarine for later collection. Unmanned aircraft (UA) fly continuously through the National Airspace System (NAS) at low altitude to monitor and map the declining radiation contours, at medium altitude to map cleanup operations, and at high altitude to relay control commands and data from the nearly one hundred unmanned vehicles at work. Decontamination, refueling, and repair shops have been established in nearby Cordova to service the vehicles and aircraft and on the USS *New York* to service the boats and submersibles. It is the largest coordinated use of international air, ground, and maritime unmanned systems ever conducted.



2.3.2 African Maritime Coalition Vignette, 2030s

Location: Gulf of Guinea off the coast of Africa

Situation: An UAS and an UUV, deployed from littoral combat ship (LCS) *Freedom*, are on patrol monitoring the littoral oil infrastructure of a developing nation-state. This nation-state has recently adjusted its geopolitical stance to ally itself militarily and economically with the United States and friendly European governments.

Scenario: The *Freedom*'s UUV in its assigned patrol area detects an anomaly, a remote pipeline welder controlled by an unknown force. The underwater remote welder is positioning itself to intersect a major underwater oil pipeline. Using its organic "smart software" processing capability, the UUV evaluates the anomaly as a possible threat and releases a communications buoy that transmits an alert signal and a compressed data "snapshot" from the UUV's onboard video/acoustic sensor.

The communications buoy's low probability of intercept (LPI) data are relayed via a small tactical unmanned aircraft system (STUAS) to other units in the area and to the Joint Maritime Operations Center (JMOC) ashore. The commander on the LCS directs the UUV and the UAS to provide persistent intelligence, surveillance, and reconnaissance (ISR) and command and control (C2) relay support. Simultaneously, the UAS transmits corroborating ISR data on a suspect vessel near the UUV anomaly. Thanks to a recently fielded, advanced technology propulsion upgrade, the STUAS is able to stay on station for 24 hours before being relieved (see graphic right).

Meanwhile, the JMOC analysts recognize the pipeline welder in the UUV data snapshot as one recently stolen and acquired by rebel antigovernment forces. The JMOC then dispatches an Allied quick reaction force (QRF) via 160th Special Operations Aviation Regiment (SOAR) aircraft and USAF CV-22 Osprey from a nearby airfield. The JMOC retasks a special warfare combatant-craft crewman (SWCC) Mk V to

2783 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

investigate and neutralize the potential hostile surface vessel controlling the stolen pipeline welder. The SWCC Mk V launches its own small UA to provide a low-level ISR view ahead of its navigation track while providing an LPI secure communications path among the special forces QRF team. The SWCC Mk V's UA provides a real-time common data link (CDL) common operational picture (COP) data stream via the higher altitude UAS to the LCS and JMOC.

The JMOC receives a signals intelligence (SIGINT) alert that the suspect hostile surface vessel is launching a Russian Tipchak, a medium-altitude, long-endurance (MALE) UA. The latest Tipchak variant is a hybrid UA with US-derived systems and avionics. This Tipchak is capable of launching short-range air-to-air missiles (AAMs) or air-to-surface missiles (ASMs). Its host platform, the suspect hostile vessel, has an early warning suite and has probably detected the LCS nearby or visually sighted the SWCC Mk V's UA. An update to the SIGINT alert at the JMOC reveals the Tipchak is being launched for a surveillance sweep and counter-air/counter-UA mission.

Realizing the hostile UA could pose a risk or even jeopardize the QRF, the JMOC commander launches a USAF MQ-1000 UA optimized for air interdiction and ground strike. The MQ-1000 UA, empowered by rules of engagement (ROE) allowing autonomous operation, immediately conducts an air-to-air engagement and neutralizes the Tipchak UA.

The SWCC Mk V's special forces team then conducts a visit, board, search, and seizure (VBSS) on the suspected hostile vessel supporting the UUV pipeline interdictor. Since the threat is neutralized, the unmanned systems update their patrol status, cancel the alert status, and recover or resume their assigned patrol sectors.

2.3.3 Complex Unmanned Systems Test and Evaluation Scenario

As unmanned systems become more complicated, more integrated, more collaborative, and more autonomous, establishing test-driven development constructs and infrastructure for supporting early-onset test and evaluation (T&E) and life-cycle T&E will become increasingly

> "The key to successful acquisition programs is getting things right from the start with sound systems engineering, cost estimating, and developmental testing early in the program cycle. The bill that we are introducing today will require the Department of Defense to take the steps needed to put major defense acquisition programs on a Sound footing from the outset. If these changes are successfully implemented, they should help our acquisition programs avoid future cost overruns, schedule delays, and performance problems."
> *–Senator Carl Levin, Chairman, Senate Armed Services Committee*
>
> "The Weapon System Acquisition Reform Act of 2009 is an important step in efforts to reform the defense acquisition process. This legislation is needed to focus acquisition and procurement on emphasizing systems engineering; more effective upfront planning and management of technology risk; and growing the acquisition workforce to meet program objectives."
> *–Senator John McCain, Ranking Member, Senate Armed Services Committee*

critical. The Weapon Systems Acquisition Reform Act (WSARA) of 2009 sets the stage for

2784 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

advancing T&E that will address cost saving through early-on engagement and effective sustainment in facilitating unmanned systems acquisition.

The two previous vignettes have focused on the utility of unmanned systems, but it is also helpful to focus on unmanned systems acquisition. The acquisition of systems with increasing net-centricity and automated functionality will introduce unexpected levels of risk. Systems engineering involves decomposing a design into separable elements, characterizing the intended relationships between them, and verifying the system built to specification operates as intended. The systems engineering "V" represents decomposition and design on the downstroke and integration, verification, and validation on the upstroke. As systems become more complex, the difficulties of addressing the upstroke of the "V" increase. T&E is critical for addressing this risk. The systems engineering of complex systems is gets scrutinized when major problems lead to program delays, cost overruns, and even cancellations. The issues typically lie with unintended and unanticipated interactions between elements that are uncovered only during integration, testing, or once in service. The T&E of manned systems has created optimal strategies for reducing risk in the areas of frequency, performance, support systems, and safety. The primary challenge for today's defense acquisition system is to execute acquisition programs without major schedule delays and cost overruns. Meeting that challenge has been the goal of acquisition reform improvements for decades.

Unmanned systems raise new issues of artificial intelligence, communications, autonomy, interoperability, propulsion and power, and manned-unmanned (MUM) teaming that will challenge current T&E capabilities. These problems will get more serious as systems become more interactive and more automated. Failures often occur at the interfaces between system elements, in many cases, between interfaces thought to be separate. The exponential trends in software and network communications increasingly mean that many elements of a system can now affect one another. The incredible complexity of millions of lines of software requires new approaches for detecting problems earlier in the design phase where cost mitigation is most effective. As systems get much of their functionality from software and multisystem interactions, complexity is no longer separate and distinct. Complexity is about the whole ecosystem, and systems engineering has to become more holistic. Model-based systems engineering, already in use by the software and circuit industries, is augmenting document-driven approaches in important ways. Executable models can be effective conveyors of information throughout a supply chain. Models designed to provide contextual information about the degrees of freedom and the interactions could potentially pass from the Government to the prime supplier and on to second- and third-tier suppliers from early concept through Milestones A, B, and C into the operations and support phase.

Location: DoD T&E Centers Across the World

Situation: In a rapid acquisition support environment, integrated T&E teams work with trainers and the user to accelerate the production of unmanned systems. The model involves industries that must leverage test frameworks to take advantage of Moore's Law advances that are exploitable every 18 months. The same technologies are actually subcomponents in the payload, communication, command system, and remote sensor support systems that currently compose various unmanned system of systems configurations.

2785 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Scenario: Warfighters need next-generation system capability to support an 18-month battlespace fielding requirement. The system involves new sensors supporting a remote sensor team. The platform will utilize several new algorithms to mitigate human support functions limited by human reaction time and communication anomalies. The platform will also have new decision algorithms supporting mission functions due to new payload capabilities. The system will use a new communication protocol evaluation system for onboard teams and for ground control teams communicating over a series of relay station and satcom grids. Platform support includes mission-driven T&E to validate autonomous support capabilities enabling nonlethal support functions. This migration will use technology for air traffic management that the Federal Aviation Administration (FAA) and DoD are co-evaluating for the automated notification of an aircraft's position to ground-based controllers as well as to other manned and unmanned aircraft.

The support situation calls for an assessment of the latest Standardization Agreement (STANAG) recovery algorithms in the event of communications link disruption with collaborating manned and unmanned systems supporting a teaming operation. Interoperability tests will be necessary to support several new services and remote service support teams translating data from the payload. The teams will leverage mission information from a variety of semantic databases across the Defense Grid to generate actionable intelligence. A new aspect of this deployment will involve the utilization of both trainers and users interacting with simulators to explore the adequacy of human systems integration algorithms to discover problems for algorithm refinement and problem discovery. Red team T&E technology will expand scenario assessment to provide forecasting without historical data using Bayesian probability models utilizing expert opinions. The T&E system will be designed to determine false positives, false negatives, dynamic limits, and integrity limits regarding mission effectiveness, suitability, survivability, and effectiveness. This wholesale advancement in T&E will result in a tenfold reduction in cycle time and cost.

2786 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

3 CURRENT STATE

Over the past decade, unmanned systems have played an increasing role in U.S. military operations. DoD uses a vast array of unmanned systems, from underwater to the upper regions of the atmosphere, from the size of a matchbox to the size of a Boeing 737.

These unmanned systems continue to prove their value in combat operations in Afghanistan, where military operations are planned and executed in extremely challenging environments. Adversaries are fighting using increasingly unconventional means, taking cover in the surrounding populations, and employing asymmetric tactics to achieve their objectives. In future conflicts, we must be prepared for these tactics as well as a range of other novel methods, including so-called "hybrid" and anti-access approaches to blunting U.S. power projection. Unmanned systems will be critical to U.S. operations in all domains across a range of conflicts, both because of capability and performance advantages, and the ability for unmanned systems to take greater risk.

As unmanned systems have proven their worth on the battlefield, DoD has allocated an increasing percentage of its budget to developing and acquiring these systems. Table 1 below reflects the budget request allocated to the three unmanned domains: air, ground, and maritime.

Table 1. 2011 President's Budget for Unmanned Systems ($ Mil)

2787 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Although unmanned systems have experienced widespread growth in funding, current world economic conditions and DoD initiatives necessitate increased efforts and focus toward the acquisition of affordable and convergent systems. DoD must continue to support diverse mission sets and capabilities, but must focus on acquiring Joint and interoperable platforms, systems, software, architecture, payloads and sensors due to today's increasingly austere fiscal environment. In addition, the ability for commanders to take risks with unmanned vehicles depends significantly on their cost. In order to be expendable, which is often the intent of building an unmanned system, the vehicle must be low-cost. The importance of procuring common platforms with core C2 systems cannot be overstated as it will yield enormous collective benefits by reducing training costs, reducing supply chain diversity, improving availability, and offering a cost-effective procurement path by exploiting the benefits of scale and software/technology reuse.

> Eliminate redundancy within warfighter portfolios.
>
> *–Under Secretary of Defense Memorandum for Acquisition Professionals, Better Buying Power, September 2010*

The cost overruns, schedule slips, and sustainability issues of unmanned systems cannot go unnoticed or unanswered. Operational T&E is not sufficient for addressing budget, schedule, and sustainment issues in unmanned systems acquisition. WSARA 2009 guidance set the stage for leveraging developmental T&E as a key factor in T&E strategy to address Milestone A and B test challenges. Unmanned system T&E must not only consider physics effects but other areas that have an effect on algorithm development such as human factors, autonomous functionality, peering, collaboration, and autonomy-driven, red-team-based T&E limit testing. The goal to gradually reduce the degree of human control and decision making required for the unmanned portion of the force structure will mean that autonomous functionality will gradually increase and new ways to test this functionality will be required.

The need to maintain simplicity and overcome bureaucracy in unmanned system acquisition is an ongoing challenge. As these programs transition to acquisition programs, there is a unique opportunity to enable productive process and oversight appropriate to producing safe, suitable, survivable, and effective systems in a rapid acquisition framework.

There is a need to leverage OA and open interfaces to overcome the problems associated with proprietary robotic system architectures. Standards and interface specifications need to be established to achieve modularity, commonality, and interchangeability across payloads, control systems, video/audio interfaces, data, and communication links. Standardization will enhance competition, lower life-cycle costs, and provide warfighters with enhanced unmanned capabilities that enable commonality and joint interoperability on the battlefield.

2788 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Addressing factors inhibiting the growth of unmanned systems will provide more interoperability, more autonomy, better artificial intelligence, better communications, human systems integration, training standardization, more propulsion and power options, and better MUM teaming. These factors are addressed through the Joint Capability Integration and Development System (JCIDS) process.

3.1 Requirements Development and Systems Acquisition

There has been substantial growth in unmanned platforms of all sizes and shapes with a corresponding increase in payload numbers and capability. Many of these systems have been rapidly acquired and immediately fielded for warfighter use through the Joint Urgent Operational Needs (JUON) process. JUONs have successfully added significant capability to joint warfighting. While those unmanned systems were rapidly developed to meet the immediate needs of the warfighter in the short term, they have not undergone rigorous requirements review and joint coordination through the normal JCIDS process, to include systems interdependencies and interoperability. Further, their long term affordability, sustainability, and potential to contribute to long term enterprise-wide capability portfolios have not been fully considered. Consequently, they have not received due consideration in the context of broader joint capability areas (JCA) which provide structure and organization to Requirements Development.

DoD is moving toward revision of the JCIDS process which will streamline urgent and deliberate Capability Development to enable requisite timeliness in meeting warfighter needs, while giving important consideration to long term affordability and sustainability. JCIDS is a key supporting process for DoD acquisition and Planning, Programming, Budgeting, and Execution (PPBE) processes. It ensures the capabilities required by the warfighter are identified with their associated operational performance criteria in order to successfully execute the missions assigned. This process allows better understanding of the warfighting needs early in capability development and provides a more comprehensive set of valid prioritized requirements. The Department's acquisition arm can then focus on choosing options to meet well defined requirement capability.

Given today's highly constrained fiscal environment, it is imperative that the Department look at many areas where efficiencies can be gained to create unmanned systems that are both effective and affordable. The DoD will look at capitalizing upon commonality, standardization, and joint acquisition strategies among others. Also, the Department demands these unmanned systems be affordable at the outset and not experience significant cost growth in their development and production evolution. Additionally, it must provide the PPBE process with affordability advice by assessing the development and production lifecycle cost at the outset.

Capability requirements, validated by the JCIDS process, inform prioritization activities in the competition for funding during the PPBE process. The objective of the PPBE process is to provide the best mix of forces, equipment, and support attainable within fiscal constraints according to DoD Directive 7045.14, *Planning, Programming, Budgeting System (PPBS)*. To meet this objective, the PPBE process aims to meet goals established by the President and the Secretary of Defense (SECDEF) in the Strategic Planning and Joint Planning Guidance. In the PPBE process, the Services match available resources (fiscal, manpower, material) against validated requirements to achieve the strategic plan. A key task is to develop a

2789 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

balanced/affordable capabilities-based Service program objective memorandum (POM). The POM position for the capability to meet a given requirement is reviewed by OSD and the final position becomes the President's Budget.

The Joint Capability Areas (JCAs)[2] are currently the preferred method the Department of Defense uses for reviewing and managing capabilities. The JCA framework provides the structure around which capabilities and capability gaps can be aligned across the Department and across the various portfolios to correlate similar needs, leverage effective solutions, and synchronize related activities. Also, various frameworks, such as the Universal Joint Task List (UJTL), are readily available to aid in identifying and organizing the tasks, conditions and required capabilities.

3.2 Unmanned Systems Applied to Joint Capability Areas

Mapping current and projected unmanned systems against the JCAs provides a sense of the Product Line Portfolio of unmanned systems and how it currently, and could in the future, contribute to the missions of the Department. Each JCA represents a collection of related missions and tasks that are typically conducted to bring about the desired effects associated with that capability. Nine Tier One JCAs are defined, and assessments identified that unmanned systems have the potential to be key contributors for Battlespace Awareness, Force Application, Protection, Logistics, and Building Partnerships. Although assessments have not yet been completed for the Force Support and Net Centric capability areas, missions and tasks in those JCAs receive significant support from unmanned systems as well.

Current technology and future advancements can and will enable single platforms to perform a variety of missions across multiple capability areas. This represents an opportunity for the Department to achieve a greater return on investment. Furthermore, the projections show that there will be opportunities for joint systems to conduct missions for each of the Services, just as there will be situations in which domain conditions or Service missions will dictate unique solutions. Detailed descriptions of each of the systems identified for the capability areas, including specific tasks, performance attributes and integrated technologies can be found at the Unmanned Warfare Information Repository site: **https://extranet.acq.osd.mil/uwir/**. Below are the descriptions for the most relevant JCA.

3.2.1 Battlespace Awareness (BA)

Battlespace Awareness is a capability area in which unmanned systems in all domains have the ability to significantly contribute well into the future to conduct ISR and environment collection related tasks. To achieve this, unmanned systems development and fielding must include the Tasking, Production, Exploitation, and Dissemination (TPED) processes required to translate vast quantities of sensor data into a shared understanding of the environment. There are many ongoing efforts to streamline TPED processing. Applications in this JCA range from tasks such as aerial and urban reconnaissance, which is performed today by Predators, Reapers and Global Hawks in the air and by PackBots and Talons on the ground, to tasks such as Expeditionary Runway Evaluation, Nuclear Forensics, and Special Reconnaissance. In the future, technology will enable

[2] http://www.dtic.mil/futurejointwarfare

2790 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

mission endurance to extend from hours to days to weeks so that unmanned systems can conduct long endurance persistent reconnaissance and surveillance in all domains. Because unmanned systems will progress further with respect to full autonomy, on-board sensors that provide the systems with their own organic perception will contribute to Battle Space Awareness regardless of their intended primary mission. This capability area is one that lends itself to tasks and missions being conducted collaboratively across domains, as well as teaming within a single domain.

3.2.2 Force Application (FA)

Force Application is another JCA which includes a proliferation of unmanned systems contributing to maneuver and engagement. Today, Predator, Reaper and Gray Eagle UAS are weaponized to conduct offensive operations, irregular warfare, and high value target / high value individual prosecution, and this trend will likely continue in all domains. In the air domain, projected mission areas for UAS include air-to-air combat and suppression and defeat of enemy air defense. On the ground, UGVs are projected to conduct missions such as non-lethal crowd control, dismounted offensive operations, and armed reconnaissance and assault operations. In the maritime domain, UUVs and USVs are projected to be particularly suited for mine laying and mine neutralization missions.

DoD personnel must comply with the law of war, including when using autonomous or unmanned weapon systems. For example, Paragraph 4.1 of DoD Directive 2311.01E, DoD Law of War Program, May 9, 2006, requires that: "[m]embers of the DoD Components comply with the law of war during all armed conflicts, however such conflicts are characterized, and in all other military operations." Current armed unmanned systems deploy lethal force only in a fully human-operated context (level 1) for engagement decisions. For these systems, the decisions both to employ force and to choose which specific target to engage are made by a human. The United States operates defensive systems for manned ships and installations that have human-supervised autonomous modes (level 3), and has operated these systems for decades. For the foreseeable future, decisions over the use of force and the choice of which individual targets to engage with lethal force will be retained under human control in unmanned systems.

3.2.3 Protection

Protection has particular unmanned systems applicability to assist in attack prevention or effects mitigation. Unmanned systems are ideally suited for many protection tasks that are deemed dull, dangerous or dirty. As the future enables greater automation with respect to both navigation and manipulation, unmanned systems will be able to perform tasks such as fire fighting, decontamination, forward operating base security, installation security, obstacle construction and breaching, vehicle and personnel search and inspection, mine clearance and neutralization, sophisticated explosive ordnance disposal, casualty extraction and evacuation, and maritime interdiction. In the Protection JCA teaming within domains and collaboration across domains will likely prevail.

3.2.4 Logistics

The Logistics joint capability area is also ideally suited for employing unmanned systems in all domains to deploy, distribute, and supply forces. Transportation of supplies is an applicable, routine task, particularly suited for unmanned systems in all types of ground terrain.

2791 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Maintenance related tasks such as inspection, decontamination, and refueling can be performed by unmanned systems. Munitions and material handling, and combat engineering are ideal tasks that can be allocated to unmanned systems to enhance safety as well as increase efficiency. Additionally, casualty evacuation and care, human remains evacuation, and urban rescue can also be tasks performed by unmanned systems. Unmanned systems will perform Logistics tasks on home station as well as forward deployed.

Table 2. DoD Unmanned Capabilities by Program below is a sample mapping of JCA tasks to the current unmanned inventory and is provided for determining current unmanned systems capabilities.

3.3 Unmanned Aircraft Systems (UAS)

The air domain has received the greatest concentration of visibility as DoD has embraced unmanned technologies. Table 1 depicts that UAS investments will continue to consume a large share of the overall DoD investment in unmanned systems. These efforts have fielded a large number of UAS capable of executing a wide range of missions. Originally, UAS missions focused primarily on tactical reconnaissance; however, this scope has been expanded to include most of the capabilities within the ISR and battlespace awareness mission areas. UAS are also playing a greater role in strike missions as the military departments field multiple strike mission-capable weapon systems for time-critical targeting. Figure 1 below illustrates the variety of platforms in today's force structure.

DoD Unmanned Aircraft Systems (As of 1 JULY 2011)

Figure 1. DoD UAS

As the number of fielded systems has expanded, flight hours have dramatically increased as depicted in Figure 2.

2795 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

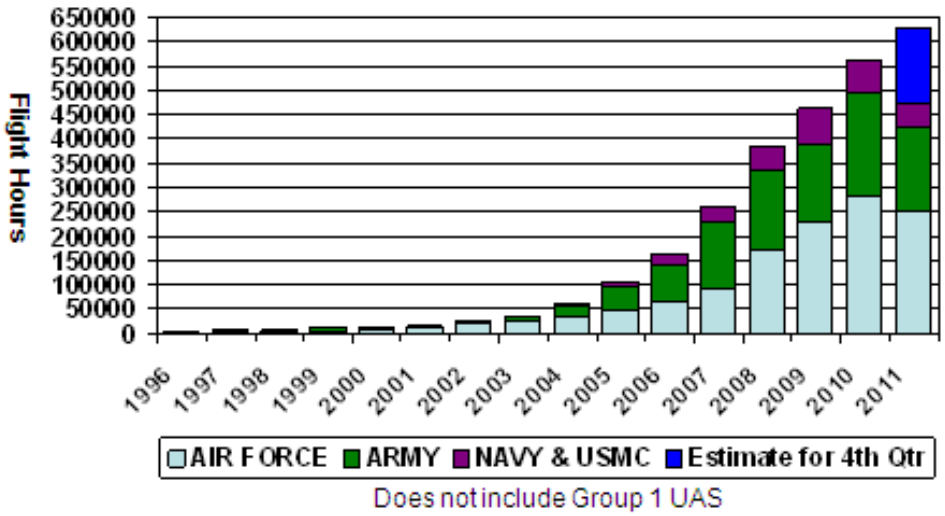

Figure 2. UAS Flight Hours (1996–Present)[3]

In 2009, DoD completed almost 500,000 UAS flight hours just in support of Operation Enduring Freedom and Operation Iraqi Freedom. In May 2010, unmanned systems surpassed one million flight hours and in November 2010 achieved one million combat hours. As these systems continue to demonstrate their value, this number will continue to grow.

> … remotely piloted vehicles have flown more than 21,000 sorties so far this year, already surpassing the roughly 19,000 drone flights last year.
>
> – *"U.S. Uses Attacks to Nudge Taliban Toward a Deal," New York Times, October 15, 2010.*

3.4 Unmanned Ground Systems (UGS)

Since operations in Iraq and Afghanistan began, DoD has acquired and deployed thousands of UGS. These systems support a diverse range of operations including maneuver, maneuver support, and sustainment. Maneuver operations include closing with and neutralizing the enemy using speed and firepower. Maneuver support missions include mitigating natural and artificial obstacles and hazards. Sustainment missions leverage maintenance and support UGVs associated with combat services support.

Approximately 8,000 UGVs of various types have seen action in Operation Enduring Freedom and Operation Iraqi Freedom. As of September 2010, these deployed UGVs have been used in over 125,000 missions, including suspected object identification and route clearance, to locate and defuse improvised explosive devices (IEDs). During these counter-IED missions,

[3] Updated 30 June 2011.

2796 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Army, Navy, and USMC explosive ordnance teams detected and defeated over 11,000 IEDs using UGVs, such as the one depicted in Figure 3.

Figure 3. Talon Ordnance Disposal Robot Preparing to Unearth Simulated IED

The lessons collected on the battlefield must be translated into programs that can be sustained. The rapid fielding and proliferation of unmanned systems and the subsequent battlefield modernization they provided have met the mission, but resulted in configuration and maintenance challenges. These ground systems continue to provide tremendous benefit to the ground commander, but improvements in user interfaces, reliability, survivability, and advances in 360° sensing, recording fidelity, and CBRN and explosive detection are required to meet the challenges anticipated in future conflicts. Figure 4 shows the UGS Family of Systems (FoS).

> On Gordon's (UGV) final days, he was launched out of the truck and was searching an intersection for a possible deep buried IED. As he was on his way to the intersection, the IED was detonated about 10 ft from his location. Still functioning, he continued to search the area. On the opposite side of the road, another IED was detonated and had turned him upside down. Everything was still working until a fire fight started.
>
> Gordon took 7 rounds to the underside and was done for the day. I took him to the robot shop for repair. It took 3 days. When he was returned to us, I put him back in the truck to get him back on duty. But this was shortly lived as he was searching a gate at a house for possible booby-traps that detonated directly next to him. Gordon was mangled beyond repair. Now his replacement "Flash" is here to finish his job.

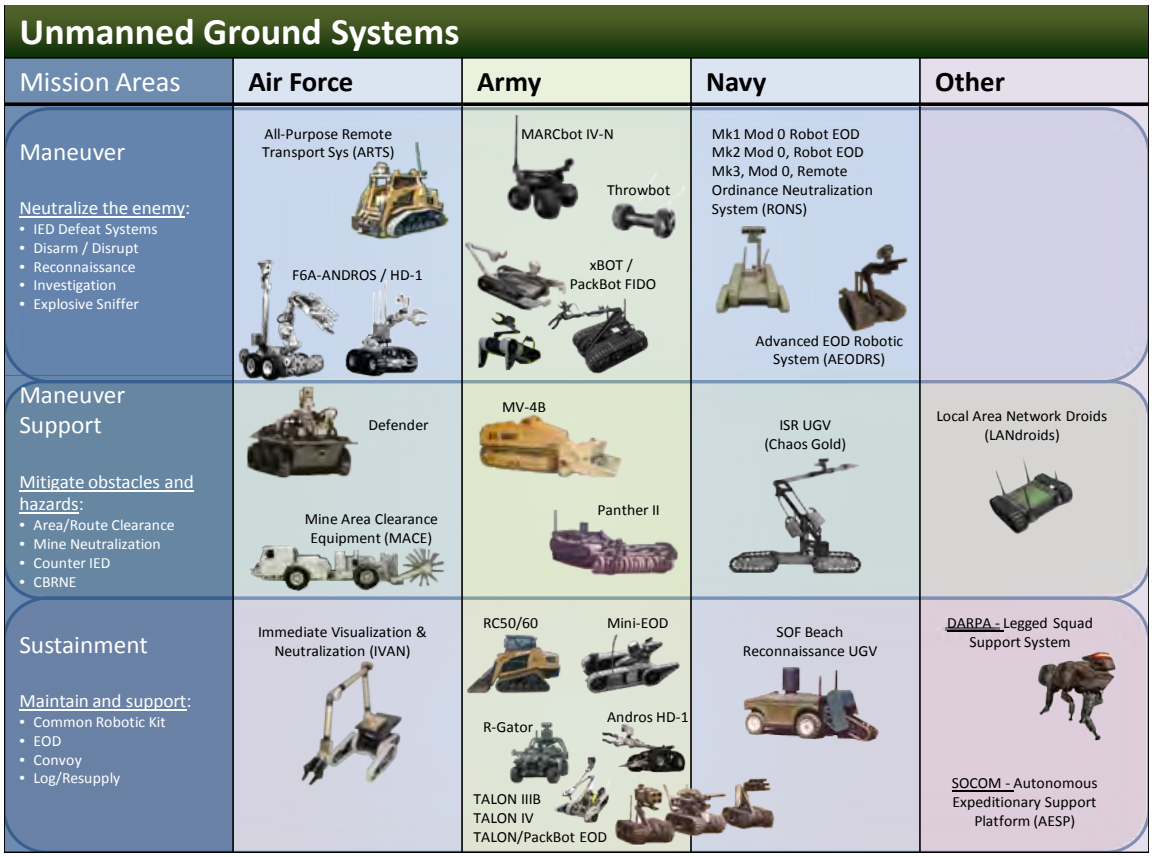

Figure 4. UGS FoS

3.5 Unmanned Maritime Systems (UMS)

Over 90% of the information, people, goods, and services that sustain and create opportunities for regional economic prosperity flow across the maritime domain. With emerging threats such as piracy, natural resource disputes, drug trafficking, and weapons proliferation, a rapid response capability is needed in all maritime regions. DoD continues to expand the range of missions supported by unmanned systems in the maritime domain. A recent study concluded

> USVs, along with UUVs, will have an important role in the conduct of MCM [mine countermeasures] as they are particularly well suited for the 'dirty - dull - dangerous' tasks that MCM entails. They provide persistence, which permits significant mine hunting and sweeping coverage at lower cost by multiplying the effectiveness of supporting or dedicated platforms. Additionally, they provide the potential for supporting an MCM capability on platforms not traditionally assigned a mine warfare mission.
>
> *– USV mission descriptions, The Navy Unmanned Surface Vehicle Master Plan, 23 July 2007*

2798 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

that unmanned maritime systems "have the potential to provide critical enabling capabilities for current NATO [North Atlantic Treaty Organization] maritime missions that can improve Alliance security and stability".[4]

Like UAS and UGS, UMS have the potential to save lives, reduce human risk, provide persistent surveillance, and reduce operating costs. UMS priority missions are listed below.

UMS can be defined as unmanned vehicles that displace water at rest and can be categorized into two subcategories: unmanned underwater vehicles (UUV) and unmanned surface vehicles (USV). USVs are UMS that operate with near-continuous contact with the surface of the water, including conventional hull crafts, hydrofoils, and semi-submersibles.[5] UUVs are made to operate without necessary contact with the surface (but may need to be near surface for communications purposes) and some can operate covertly.

The use of UMS is not new. After World War II, USVs were used to conduct minesweeping missions and test the radioactivity of water after each atomic bomb test. Another example occurred during the Vietnam War in an area south of Saigon, where remotely controlled USVs conducted minesweeping operations. More recently, UUVs conducted mine-clearing activities during Operation Iraqi Freedom in 2003. A complementary suite of UMS serve as the foundation for MCM operations from the Littoral Combat Ship (LCS) and small diameter UUVs are currently the main mine detection capability for ports & harbor and in the Very Shallow Water zone.

At a recent Science and Technology Conference hosted by the Office of Naval Research, Chief of Naval Operations (CNO) Admiral Gary Roughead made a number of statements expressing UMS goals for the Department of the Navy. Solving the power consumption problem would be the "one thing" CNO would most like to see the Navy's scientists accomplish.[6] Rear Admiral Nevin Carr, Chief of Naval Research, explained the current efforts in filling the needs in this unmanned maritime area and went on to describe where and how this technology might be applied in the future: "Two options are under exploration: fuel-cell technologies and radioscope thermoelectric generators that can provide low amounts of power for very long periods of time. We might start thinking about setting up drone refueling stations. You might deploy a remotely manned underwater generator that sits on the bottom in a secure area, which is a secure location where your forward-deployed vehicles might come back and recharge."

Figure 5 illustrates the variety of platforms and maritime missions supporting today's operations by UMS and those planned for operation in the near future. They have the potential

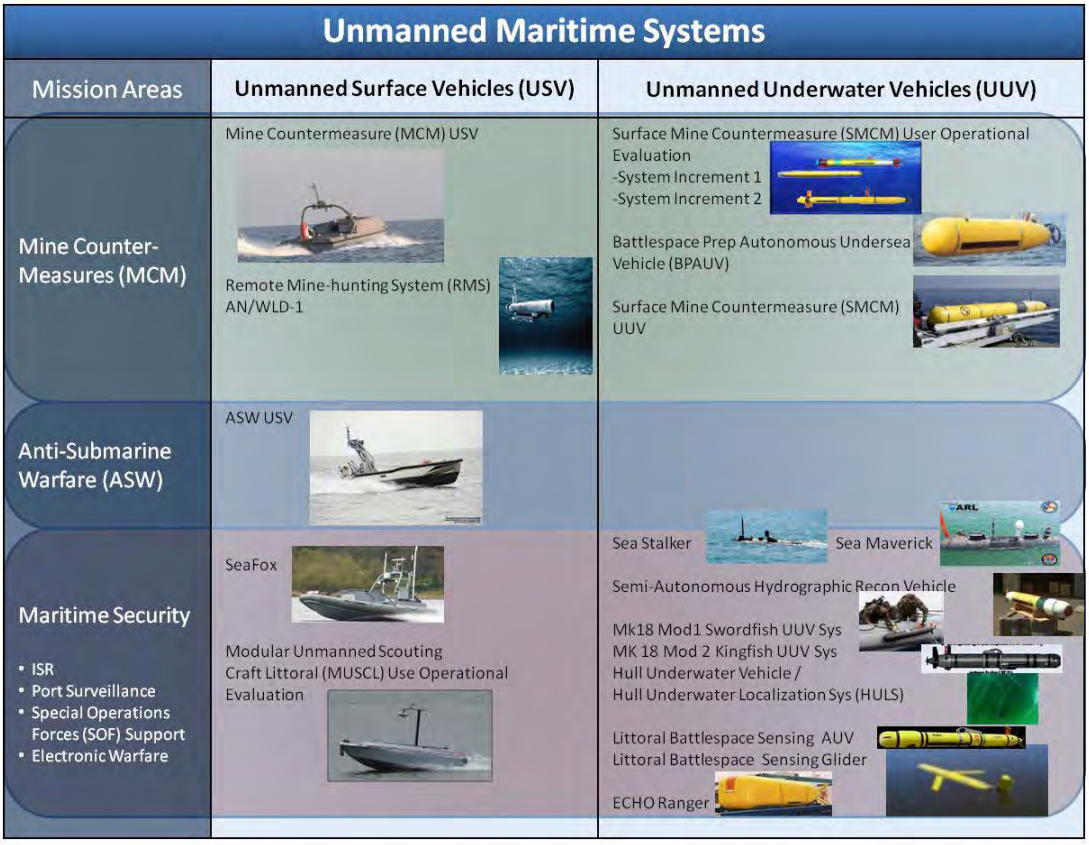
2799 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

for even greater integration, especially UUVs, to the point of assisting the current submarine and surface fleet in replacing fixed underwater sensor grids; using UUVs and distributed netted sensors to expand our submarine's sphere of influence; and weaponizing UUVs.

However, there are currently limitations to realizing the full potential of UMS:

- Endurance
- Underwater C2 and deconfliction
- Survivability in an unforgiving environment
- Launch and recovery
- Communication technology for dynamic tasking, querying, and data dissemination

These challenges are areas for further technical exploration. Despite these challenges, the future for UMS is very promising. Building on the experience and contribution from this first generation of fielded UMS, the shift is underway from UMS merely serving as an extension of the sensor systems of manned ships and submarines into an integrated FoS to provide full mission capabilities with increased autonomy.



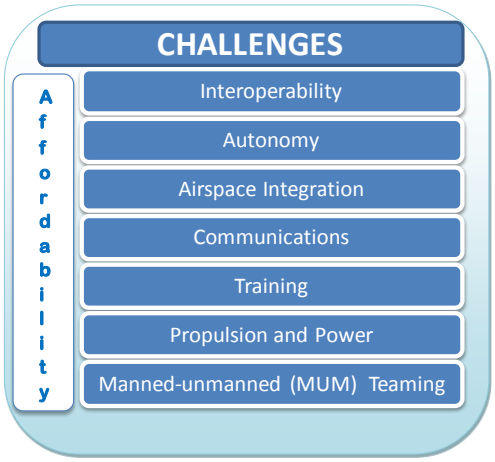


Figure 5. DoD UMS FoS

2800 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

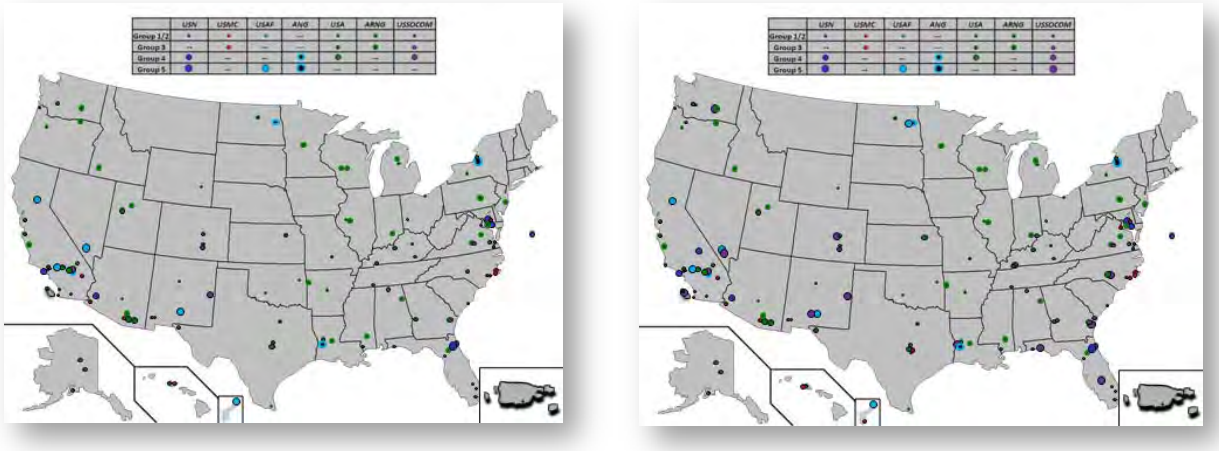
3.6 Challenges for Unmanned Systems

The number of fielded systems and the range of missions supported by unmanned systems continue to grow at a dramatic rate. As DoD steers a path toward the vision described in Section 2, the challenges listed on the right must be overcome in order to realize the full potential offered by unmanned systems. The following subsections summarize these challenges and the remainder of this document provides details and future goals for dealing with each challenge.

3.6.1 Interoperability

To maximize the potential of unmanned systems, the systems must be capable of operating seamlessly with each other and with manned systems across the air, ground, and maritime domains. System interoperability is critical in achieving these objectives and requires the implementation of mandated standards and Interoperability Integrated Product Team (I-IPT) profiles. Properly implemented, interoperability can serve as a force multiplier, improve joint warfighting capabilities, decrease integration timelines, simplify logistics, and reduce total ownership costs (TOC). One of the most powerful tools in maximizing interoperability and achieving these objectives is the adoption of the open systems architecture concept.

3.6.2 Autonomy



The rapid proliferation of unmanned systems and the simultaneous operation of manned and unmanned systems as unmanned systems expand into additional roles have created a manpower burden on the Services. With limited manpower resources to draw upon, the Services are seeking ways to improve the efficiency of operations. For instance, introducing a greater degree of system autonomy will better enable one operator to control more than one unmanned system, and has the potential to significantly reduce the manpower burden. Additional benefits are greatly reducing high bandwidth communication needs and decreasing decision cycle time. Similar efficiencies can be gained by automating the tasking, processing, exploitation, and distribution (TPED) of data collected by unmanned systems. Autonomy can help extend vehicle endurance by intelligently responding to the surrounding environmental conditions (e.g., exploit/avoid currents) and appropriately managing onboard sensors and processing (e.g., turn off sensors when not needed). Implementing a higher degree of autonomy faces the following challenges:

- Investment in science and technology (S&T) to enable more capable autonomous operations
- Development of policies and guidelines on what decisions can be safely and ethically delegated and under what conditions
- Development of new Verification and Validation (V&V) and T&E techniques to enable verifiable "trust" in autonomy

2801 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

3.6.3 Airspace Integration (AI)

The rapid increase in fielded UAS has created a strong demand for access within the NAS and international airspace. The demand for airspace to test new systems and train UAS operators has quickly exceeded the current airspace available for military operations. Figure 6 shows the projected number of DoD UAS locations in the next six years, many without access to airspace compatible for military operations under the current regulatory environment.

2011 **2017**

Figure 6. Representative DoD UAS Locations from 2011 to 2017.

NAS access for UAS is currently limited primarily due to regulatory compliance issues and interim policies. DoD UAS operations conducted outside of restricted, warning, and prohibited areas are authorized only under a (temporary) Certificate of Waiver or Authorization (COA) from the FAA. The COA process is adequate for enabling a small number of flights, but does not provide the level of airspace access necessary to accomplish the wide range of DoD UAS missions at current and projected operational tempos (OPTEMPOs). This constraint will only be exacerbated as combat operations in Southwest Asia wind down and systems are returned to U.S. locations.

3.6.4 Communications

Current unmanned systems operations involve a high degree of human interaction with the systems via various means for C2 and transmission of operational data. Protection of these communication links and the information flowing through them is critical to these operations. As the number of fielded systems grows, communications planners face challenges such as communication link security, radio frequency spectrum availability, deconfliction of frequencies and bandwidth, network infrastructure, and link ranges. Intelligent means of data parsing is needed to enable TPED and counter communication challenges.

2802 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

3.6.5 Training

The rapid proliferation of numbers and types of UAS in response to wartime demand coupled with an expected redeployment of forces back to a peacetime footing will result in continuation training greater than what has been required in the past. This has caused pause to examine UAS training and to develop an overall strategy. At present, due to high demand for UAS assets in real world contingencies, most day-to-day, continuation training is accomplished under in-theater combat conditions. At the same time, disparate efforts by a number of organizations across the Department are underway to try to address UAS training requirements. As UAS forces drawdown in theater and redeploy, the Services will require comprehensive continuation and Joint force training in the peacetime environment at UAS bed-down and selected Joint training locations.

3.6.6 Propulsion and Power

The dramatic increase in the development and deployment of unmanned systems across the entire spectrum of air, ground, and maritime missions has led to a concurrent increase in the demand for efficient, powerful, often portable, and logistically supportable solutions for unmanned system propulsion and power plant requirements. As these systems continue to demonstrate their value, operators want them to function longer without refueling and to do more tasks; these demands tax the internal power sources. The laboratories of the military Services and industry are focusing their efforts to find efficient solutions to the demand for improved propulsion and power plants. Regardless of energy source, total vehicle design, from materials used to autonomous response to the physical environment, needs to be considered up front to maximize endurance.

3.6.7 Manned-Unmanned (MUM) Teaming

MUM teaming refers to the relationship established between manned and unmanned systems executing a common mission as an integrated team. U.S. military forces have demonstrated early progress in integrating unmanned systems within the existing manned force structure, but much more needs to be done to achieve the full potential offered by unmanned technology. Improving MUM teaming is both a technology challenge (such as connecting the systems) and a policy challenge (such as establishing the rules of engagement for operating semi-autonomous unmanned with manned systems).

2803 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

4 INTEROPERABILITY

4.1 Overview

There is a clear benefit for warfighters to be able to seamlessly command, control, communicate with, exploit and share sensor information from unmanned systems across multiple domains. The Unmanned Systems Interoperability Initiative (UI2) led by the OSD UAS Task Force is in the process of developing an overarching strategy for increasing unmanned systems interoperability, with the long-range vision of producing a strategy that can be leveraged across the full spectrum of both unmanned and manned systems. DoD's goal is to move from Service/Agency-unique, stand-alone capabilities toward substantially improved interoperability standards that lead to an improved collaborative operational environment.

> Lack of UAV interoperability has had a real-life impact on U.S. operations … there have been cases where a Service's UAV, if it could have gotten data to another Service, another component, it may have provided better situational awareness on a specific threat in a specific area that might have resulted in different measures being taken.
>
> *– Dyke Weatherington (PSA/UW)*

4.2 Functional Description

Interoperability is the ability to operate in synergy in the execution of assigned tasks.[7] Properly implemented, it can serve as a force multiplier, improve warfighter capabilities, decrease integration timelines, simplify logistics, and reduce TOC. DoD Directive (DODD) 5000.1 establishes the requirement to acquire systems and FoSs that are interoperable.[8] DoD's unmanned systems will need to demonstrate interoperability in a number of areas:

- *Among similar components of the same or different systems.* The plug-and-play use of different sensors on an unmanned vehicle.
- *Among different systems of the same modality.* An open common ground control station (GCS) architecture for multiple, heterogeneous unmanned vehicles.
- *Among systems of different modalities.* The ability of air, ground, and maritime vehicles to work cooperatively.
- *Among systems operated by different Military Departments under various CONOPS and TTP, i.e., in joint operations.* Joint service systems working in concert to execute a common task or mission.

[7] Definition found in Joint Publication (JP) 1-02, Department of Defense Dictionary of Military and Associated Terms, 12 April 2001 (as amended through 17 March 2009).
[8] DODD 5000.1, Enclosure 1, paragraph E1.10.

2804 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- *Among systems operated and employed by coalition and allied militaries under the governance of various concepts of employment (CONEMPs), TTPs, e.g., in multinational combined operations or NATO STANAGs.* The ability of coalition and allied systems to work in concert to execute a common task or mission based on predefined roles and responsibilities.
- *Among military systems and systems operated by other entities in a common environment.* The ability of military UAS to share the NAS and international airspace with commercial airliners and general aviation.
- *Among systems operated by non-DoD organizations, Allies, and coalition partners, i.e., in combined operations.* The ability of assets from organizations such as Customs and Border Protection (CBP) and Department of Homeland Security (DHS) to coordinate, interoperate, and exchange information with DoD assets of the same modality and same model.

> The interoperability goal for Unmanned Systems is an ability to provide data, information, material, and services to and accept the same from other systems, units, or forces … and to use the exchanged data, information, material, and services to enable them to operate effectively together.

The Joint Unmanned Aircraft Systems Center of Excellence (JUAS COE)[9] maintains the Joint CONOPS for UAS, which provides a joint vision for the operation, integration, and interoperability of UAS and touches on several of the areas mentioned above. Figure 7 illustrates joint, cross-domain interoperability.

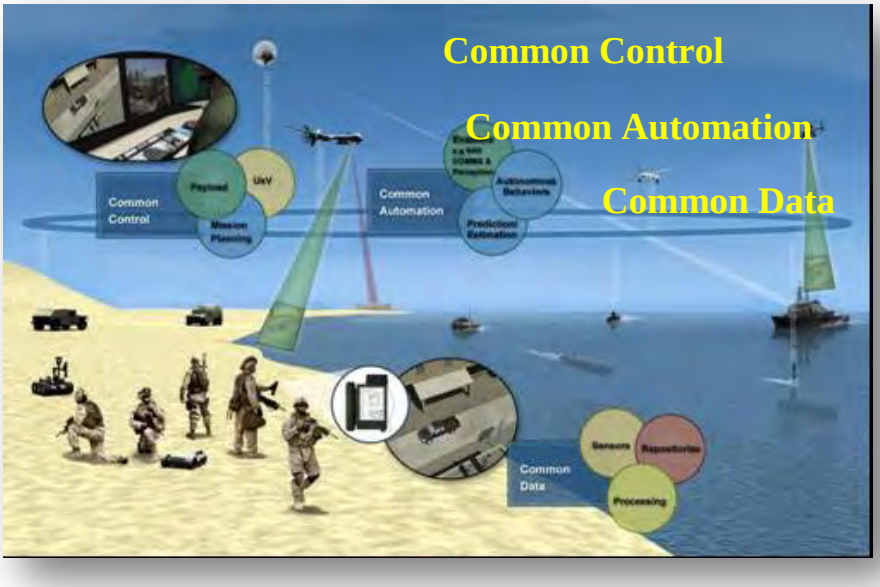


Figure 7. Joint Cross-Domain Interoperability.

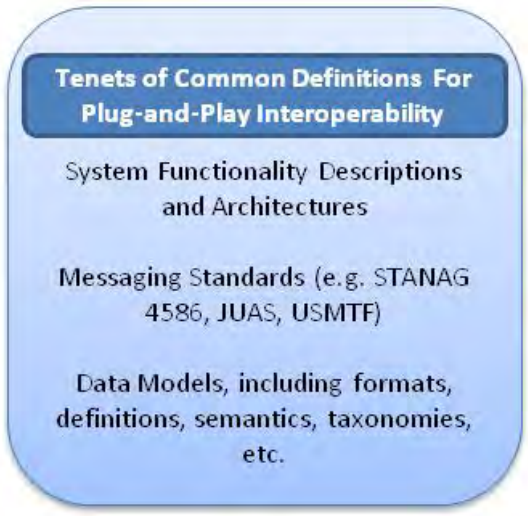
[9] JCOE is being disbanded June 2011 and its tasks are being transferred to the Joint Staff.

2805 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

4.3 Today's State

The historical approach to software and hardware acquisition relied on dedicated design for each system to accomplish a specific mission or capability. This approach may be optimal for a single system, but it unfortunately produces a collection of discrete, disjointed solutions with significant functional overlap and no method to exploit common components of each system.



Open architecture (OA) facilitates interoperability between systems by effectively leveraging the following concepts:

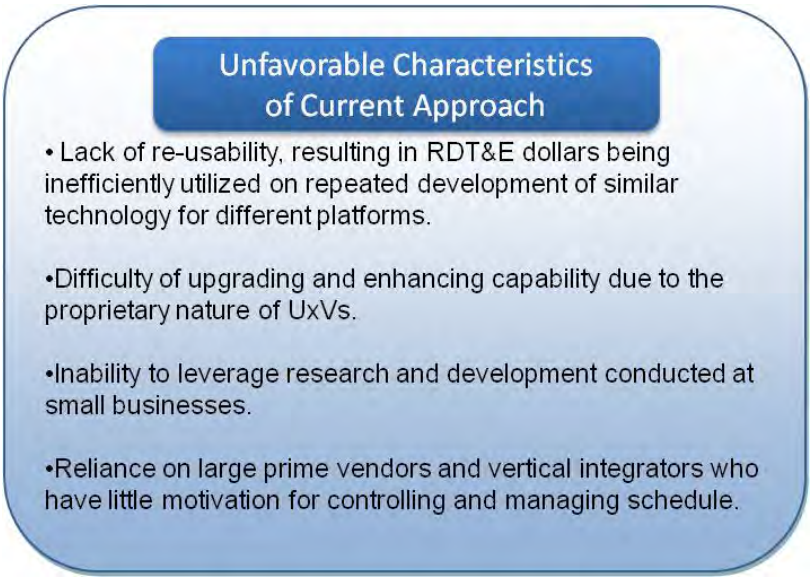
- Common capability descriptions in system requirements
- Common, open data models, standards, interfaces, and architectures in system design
- Common components in system acquisition strategies

OSD defines OA as a multifaceted strategy providing a framework for developing joint interoperable systems that adapt and exploit open-system design principles and architectures. This framework includes a set of principles, processes, and best practices that:

- Provide more opportunities for competition and innovation
- Rapidly field affordable, interoperable systems
- Minimize total ownership cost
- Optimize total system performance
- Yield systems that are easily developed and upgradeable
- Achieve component software reuse[10]

These (predominantly) acquisition issues are aided by a solid framework for software, component, and systems interoperability.

Traditionally, efforts have focused on system functionality descriptions, with interoperability focused at the messaging layer (e.g., the Joint Architecture for Unmanned Systems (JAUS) and STANAG 4586) to achieve standards-based interoperability. However, the tenets of common definitions and understanding listed on the left are required to achieve a true plug-and-play level of interoperability in which software capabilities from multiple vendors can be developed and integrated into a single system, supporting the exchange, interpretation, and action on data from other systems.



Through implementation and program-level

[10] Terms and Definitions, Defense Acquisition University, https://acc.dau.mil/CommunityBrowser.aspx?id=22108.

2806 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

adoption of these three tenets, DoD intends to address the issue of single proprietary vendor dependency within the acquisition system and improve conditions allowing for full competition.

4.4 Problem Statement

Over the last decade, the DoD has achieved great successes from the use of unmanned systems for both peacetime and wartime operations. These successes led to a significant increase in the number of unmanned systems planned and procured, and the future looks to see an exponential increase in the quantity and diversity of unmanned systems applications. Traditionally, each unmanned system was procured as a vertically integrated, vendor-proprietary solution, consisting of the vehicle system, control station, communications channels, and encryption technologies. These single-system variants were typically "closed" systems utilizing proprietary interfaces. Development of the entire system was conducted in parallel with close interdependencies between components and procured as a whole through the platform prime contractor. As the number of new unmanned systems programmed in the Service budgets increased, the magnitude of RDT&E requirements for development skyrocketed. In addition to cost, this approach resulted in a number of unfavorable acquisition and growth characteristics that impeded progress as depicted above. Further, silence about the lack of interoperability and standards failed to foster dialog on how to overcome them. Over time, this resulted in an inhibition to innovation; increased vulnerability to threats where attacks on common attributes can impact multiple systems; increased complexity to systems engineering, development, and test; increased upfront costs; increased costs to system upgrades that cannot be made without changes to the interoperable dependencies of multiple systems; and budgeting protocols that treat interservice and coalition interoperability as fiscal trade-space.

These issues have significantly hampered unmanned systems acquisition activities. However, urgent wartime needs dictated that such concerns be relegated to the background, in the interest of rapid initial deployment. As the unmanned systems industry matures, however, the acquisition process must evolve in parallel. Addressing and enabling interoperability within unmanned systems will help accomplish this goal.

4.5 The Way Ahead

The technical approach to achieve the interoperability vision leverages the tight connection between interoperability and OAs, and consists of several elements. Each of the following elements is required, and none is sufficient in its own right to implement an OA:

2807 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Development of a standard data model and service definitions that support OA concepts.
- Development of multiple repositories of models, software components, interface standards, and infrastructure services that can be used across the Services to extend, adapt, and compose unmanned systems and support software component reuse. These repositories should encourage the use of commercial, off-the-shelf (COTS) solutions where available, and are not intended to be "single point bottlenecks" as other efforts have been in the past. The goal is to provide multiple collection points across the Services for best practices, interfaces, and implementations.
- Collaboration among Government, industry, and academia to extend and manage the repositories and to validate components.
- Migration of current and developing systems to the OA approach.

To meet current interoperability standards, DoD will rely more heavily on spiral and incremental development initiatives ensuring services are compliant with these standards.

4.5.1 Open Architecture (OA)

OA utilizes a common set of interfaces and services; associated data models; robust, standard data busses; and methods for sharing information to facilitate development. OA involves the use of COTS components with published, standard interfaces, where feasible, at all levels of system design. This approach avoids proprietary, stove-piped solutions that are vendor-specific and enables innovation to be better captured and integrated into systems design. The OA approach allows for expanded market opportunities, simplified testing and integration, and enhanced reusability throughout the program life cycle. The Navy's Cruiser Modernization Program is one such effort.

The OA process encourages innovation, allows information sharing among competitors, and rewards Government and industry for this collaboration. It allows programs to include small businesses in systems acquisition activities as a valuable, affordable, and innovative source of technologies and capabilities. The result is a better product.

DoD unmanned systems consist of a wide range of programs, architectures, and acquisition approaches. To create a common framework for development and acquisition, DoD adopted principles of OA and service-oriented architecture (SOA). While the OA is the contracting, architecture, and business process methodology used to develop and acquire systems, a SOA is a specific way of designing software, in a standardized architecture, that uses interchangeable and interoperable software components called *services*. When coupled together, the result is a business approach to acquiring software developed within a common engineering construct that promotes reuse, cost reduction, competition, growth opportunity, expandability, innovation, and interoperability among similar systems.

2808 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

SOA provides a set of principles or governing concepts that are used during the phases of systems development and integration. This type of architecture attempts to package functionality as interoperable services within the context of the various business domains that use it. SOAs increase functionality by incorporating new services, which are developed separately but integrated within the system's common framework as a new capability. Their interfaces are independent of application behavior and business logic, and this independence makes the interfaces agile in supporting application changes and enables operations across heterogeneous software and hardware environments.

Programs and efforts to date have strongly tied together unmanned systems capability requirements and definitions, along with underlying technology selections. In recognition of the rapidly changing technology, unmanned systems architectures would benefit strongly from being defined at a platform-independent model (PIM) level, which is devoid of technology dependence.

The PIM level allows for definition of domains, software components, interfaces, interaction patterns, and data elements without flattening them to a specific set of computing, communications, and middleware technologies. Aside from enabling technology-independent design, this approach, as formalized in model-driven engineering principles, fosters interoperability.

At a minimum, a common set of interfaces and messaging standards is required for interoperability. Without a common semantic understanding of what data represent, there is significant opportunity for lack of interoperability, even if messages are correctly parsed and interfaces are followed. Therefore, a key final aspect is the recognition that data modeling is a separate, core aspect for defining interoperable systems. This aspect includes specifying definitions, taxonomies, and other semantic information to ensure there is a common understanding about what information a specific data item imparts.

This approach supports the involvement of multiple organizations in the development of one or more services, and results in increased innovation, flexibility, and improved performance. SOAs, however, constitute only one approach to implementation of OAs. Certain programs may not need SOAs. The program manager will determine the correct architecture to implement. Regardless of whether SOA approach is used, DoD has mandated an OA approach in software development. The program manager will be responsible for implementing an environment that will support OA in both programmatic and technical areas.

4.5.2 Service Repositories

DoD recognizes that there is rarely a one-size-fits-all solution to the challenging problem of software and service reuse. However, service repositories fill a growing need within DoD for commonality, reuse, and reduced duplication of effort, all of which aid interoperability by leveraging common interfaces. Programs will have access to the service repositories for their use in planning and implementation. In addition, programs will be encouraged to contribute services (within Government Data Rights constraints) to the repositories for future reuse. Where programs have requirements that cannot be met by software within the repositories, existing

2809 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

services may be extended to add functionality, and this approach should result in cost savings over the creation of brand new capabilities.

Constructing such repositories requires a commitment to OA, along with the adoption of existing and upcoming standards (e.g., SAE JAUS, STANAG 4586, UCS), so that a common framework exists with which to develop services. In addition, tools are necessary to ease adoption, reduce learning curves, and provide validation and certification capabilities. See Figure 8.

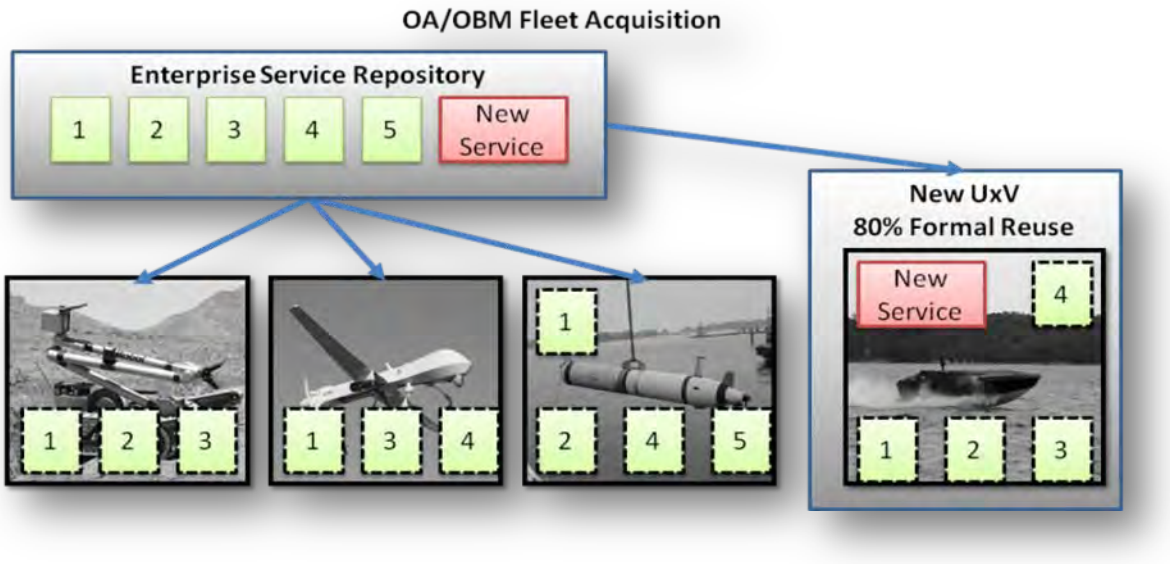


Figure 8. Cross-Domain Service Reuse Through an Enterprise Service Repository.

OA allows components to be developed once rather than redeveloped for each warfare area or mission. OA exploits software reuse and open interfaces to ensure unnecessary costs are not incurred in the redevelopment of core software. The OA approach described in this section utilizes collaboration among Government, industry, and academia to comply with principles of modularity, reusability, interoperability, affordability, and competition to develop reusable products.

Through implementation of the OA approach, DoD will develop and establish a domain service portfolio management (DSPM) repository for new acquisition and in-service programs. This repository will contain program-related software services information including standard architectures, design guidelines, service interfaces, and specifications for designing new systems or modifying existing systems. Programs will be required to consult with the DSPM repository for software reuse, where applicable. As programs design new and unique software and services, they are required to populate the DSPM repository with new information and make the service available for reuse, within Government Data Rights constraints.

4.5.3 Collaborating Communities

DoD has long recognized the value in fostering collaboration between Government, industry, and academia in open forums to address interoperability and common standards. To that end, a

2810 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

number of integrated product teams, working groups, and other communities have formed, under the auspices and support of OUSD(AT&L), to address the interoperability challenge. These forums have enabled the Government to engage with industry at all levels, from grassroots to executive, and have enabled DoD personnel to aid in the systems and architecture design process, rather than simply being customers. These collaborating communities exist within a variety of national and international standards bodies, span the domains of unmanned systems (i.e., UAS, UGS, UMS), and address key cross-domain areas as well as domain-unique capabilities. DoD intends to continue to support this type of collaboration as it fosters the development of OAs. Current examples of these communities include the following:

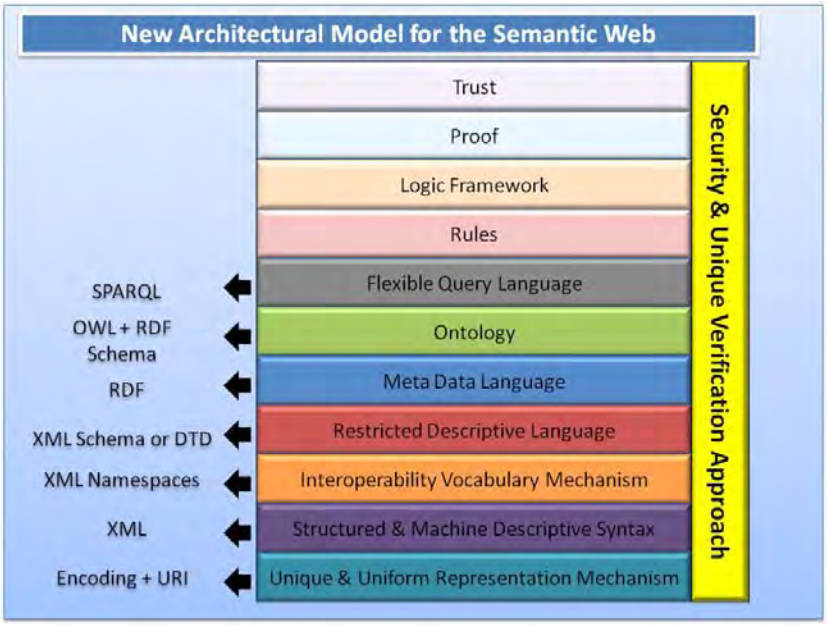
- The OUSD(AT&L)-chartered UAS Task Force to coordinate critical DoD UAS issues and develop a path to enhance operations, enable interdependencies, facilitate interoperability, and streamline UAS acquisition. Within the UAS Task Force, the I-IPT has been chartered to promote UAS interoperability across the Services. The I-IPT establishes a central coordination forum for the Services' acquisition organizations and participating industry partners to share ideas that will allow the Department to build interoperability within the deployed UAS infrastructure, individual systems, and interfaces with appropriate manned weapons systems and C2 capabilities.
- Under the guidance of the Defense Science and Technology Advisory Group, the Autonomy Systems Community of Interest (CoI) closely examine the DoD's S&T investments in the enabling of autonomous systems. Specifically, this CoI identifies potential investments to advance and initiate critical enabling technology developments and strategically assesses the challenges, gaps, and opportunities to develop and advance autonomous systems.
- The National Geospatial-Intelligence Agency (NGA) is a member of the U.S. Intelligence Community and a Department of Defense (DoD) Combat Support Agency. NGA provides support to civilian and military leaders and contributes to the state of readiness of U.S. military forces by providing geospatial intelligence (GEOINT) imagery, imagery intelligence and geospatial data (e.g., mapping, charting and geodesy), and information to ensure the knowledge foundation for planning, decision and action. NGA also contributes to humanitarian efforts, such as tracking floods and disaster support, and to peacekeeping. NGA provides unmanned systems, topographical and terrestrial data, geodesy and geophysical data, imagery and precise position and target data for unmanned system mission planning and UAS flight operations. GEOINT support includes aeronautical and safety of navigation data, vertical obstruction, digital terrain elevation data and hydrographic data.
- NATO's Joint Capability Group on Unmanned Aerial Vehicles (JCGUAV) directs interoperability efforts in unmanned aviation. JCGUAV subsumed NATO's three Military Department UAS-related groups (PG-35, Air Group 7, and Task Group 2) in 2006. Its major accomplishments to date include STANAG 4586 for UAS message formats and data protocols, STANAG 4671 for UAV Airworthiness Standard, and STANAG 7085 for the CDL communication system, which has been mandated by OSD since 1991.
- NATO's Joint Capability Group Intelligence Surveillance and Reconnaissance (JCGISR) provides interoperability between NATO and Coalition ISR systems and includes

2811 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

standards related to imagery formats and interfaces, data storage interfaces, motion imagery, electronic intelligence reporting, and imaging systems data links.

- Current UAS System Interoperability Profiles (USIPs), produced by the I-IPT, define the standard interface for payload products and the data link between a control station and air vehicle for line of sight (LOS) and beyond line of sight (BLOS) scenarios. Future USIPs will address other aspects of interoperability to include data encryption, additional data link technologies such as bandwidth efficient common data link (BE-CDL), and enhanced capabilities provided by future sensors.
- The Joint Architecture for Unmanned Systems (JAUS) began in 1995 as an effort by the Army's program office for UGVs in the Aviation and Missile Research, Development and Engineering Center (AMRDEC) at Redstone Arsenal to establish a common set of message formats and data protocols for UGVs. Deciding to convert JAUS to an international industry standard, the program office approached the Society of Automotives Engineers (SAE), a standards development organization (SDO) with robotics experience, which established the AS-4 Unmanned Systems Committee in August 2004. AS-4 has three subcommittees focused on requirements, capabilities, and interfaces and an experimental task group to test its recommended formats and protocols before formally implementing them. The migration to the SAE is complete, and the first set of SAE JAUS standards, focusing on the JAUS Service Interface Definition Language (JSIDL), core services, mobility services, manipulation services, and environmental sensing services, has been balloted and released. Although AS-4 is open to its members creating standards on other aspects of unmanned systems beyond message formats and data protocols for UGVs, much of this broader work is now being undertaken by other UAS-related SDOs. STANAG 4586 is unmanned aviation's counterpart to JAUS.
- The Navy's Program Executive Officer of Littoral and Mine Warfare (PEO(LMW)) formally adopted JAUS message formats and data protocols for use with its UUVs, USVs, and UGVs in 2005. Working through SAE AS-4, the Naval Undersea Warfare Center (NUWC) expanded JAUS to serve the UMS community. It found only 21% of UMS message formats to be directly compatible with the formats of JAUS, with the high percentage of new formats needed possibly due to the operation of UMS in three dimensions versus the two dimensions of UGVs, for which JAUS was developed. UUV variants of JAUS services are in active development and have been presented to the SAE AS-4 committees.
- Under direction from the OUSD(AT&L),[11] the UAS Task Force chartered the UAS Control Segment (UCS) Working Group, which is tasked to develop and demonstrate a common, open, and scalable UAS architecture supporting UAS Groups 2 to 5 (see Fig 1. DoD UAS for Groupings). The UCS Working Group comprises Government and industry representatives and operates using a technical society model where all participants are encouraged to contribute in any area of interest. This effort incorporates the best practices of current Army, Air Force, and Navy development efforts to include, but not limited to, the following:

[11] OUSD(AT&L) Acquisition Decision Memorandum, 11 February 2009.



2812 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Definition of a common functional architecture, interface standards, and business rules
- Use of open-source and Government-owned software as appropriate
- Competitive acquisition options
- Refinement of message sets to support all operational requirements of the systems previously defined

In addition to the definition of common capability descriptions, standards, data models, and architectures, DoD continues to promote the development of OA tools and to aid system acquisition and development in embracing the OA concepts. These efforts extend across the technology and unmanned vehicle spectrum, from software development kits, to complete architectures, addressing UGVs, UMVs, and UAVs, across all Services. Examples of such tools include:

1. The JAUS Tool Set (JTS) is a tool to help developers build JAUS-compliant software components without having to be intimately familiar with the details of JAUS. JTS allows an unmanned system designer to focus on behavior rather than messaging, protocol, and other considerations by providing a graphical user interface (GUI) service editor, validator, internal repository, C++ code generation, and hypertext markup language (HTML) document generation.

   The Navy and OSD have supported and promoted the use of the JTS and have had success incorporating it into development and acquisition efforts. Use of JTS on programs accrues benefits to a number of stakeholders in the acquisition chain and RDT&E community. These benefits include enabling a fair basis for competition among vendors so that true capabilities are evaluated; reducing vendor lock-in on unmanned systems; and enabling the development of a service repository for JAUS capabilities that have been developed and are available for reuse. JTS reduces the threshold for entry into developing JAUS-compliant systems, opens the market to small businesses, and drives competition and innovation focused on core technology. In addition, JTS provides an accepted, common validation capability, which is critical to ensure systems maintain compliance with JAUS.

2813 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. The STANAG 4586 Compliance Toolkit (4586CT) is an integrated set of software tools that provides passive, interactive, and automated test capability. Its core function is to verify the structure and content of data link interface (DLI) messages against both STANAG 4586 and "private" messages as defined to support service-, mission-, or platform-specific requirements. This nonintrusive capability is provided either in real time or during post-run analysis. Additionally, 4586CT can be interoperable with other DLI-compatible systems in either manual mode (where an engineer monitors and injects DLI messages into the network) or automated mode (in which 4586CT interacts directly with other DLI systems according to user-defined scripts and procedures).

   These capabilities enable 4586CT to perform compliance testing at both the message level and the higher protocol session levels of unmanned systems relative to the STANAG 4586, and other more specific interoperability profiles. Complex DLI message dialogs can be monitored and system interaction sequencing verified as 4586CT follows user-defined test programs. Because 4586CT can function as a proxy for other unmanned system components, it is also used during system development and task-specific integration testing to provide insight into unmanned system interaction and performance. Multiple instances of 4586CT can also be utilized to perform rapid prototyping of interoperation protocols during profile design; as a result, 4586CT can be a useful tool during the development of interoperability standards themselves.

The T&E of interoperability continues to evolve with the growth of unmanned systems. The C2 of these systems presents unique test challenges as autonomous functionality expands to operating complex equipment over wireless links. The spectrum of test includes assessment of standards compliance, electromagnetic frequency testing, sensor standards, payload standards, systems interoperability, quantifiable task assessment, performance measurement, metrics development, congestion management, and performance baseline measures. The scope of operation includes operator, platform, communications grid, C2 teams, ground stations, sensor teams, and collaborating systems. While today's test represents a migration of the test challenge represented by proprietary data exchange and data formats towards service-oriented architecture exchange, it is also conceivable that the cognitive nature of unmanned systems algorithm development may actually accelerate the need for semantic knowledge exchange T&E.

The rapid acquisition of quickly evolving unmanned systems will require an unmanned systems T&E capability that evolves at a pace that exceeds this evolution. The T&E of unmanned systems interoperability requires investment in information architectures, methodology, test scenario synthesis, model-based T&E, and cross-UAS usage case repositories.

4.5.4 System Migration

Services working with OUSD(AT&L) are exploring the business case for adopting an OA approach for current and in-development systems. While various challenges still remain in the adoption of OA, the goal in the next 12 months is to identify migration pathways for all current programs of record (see Figure 9).

2814 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

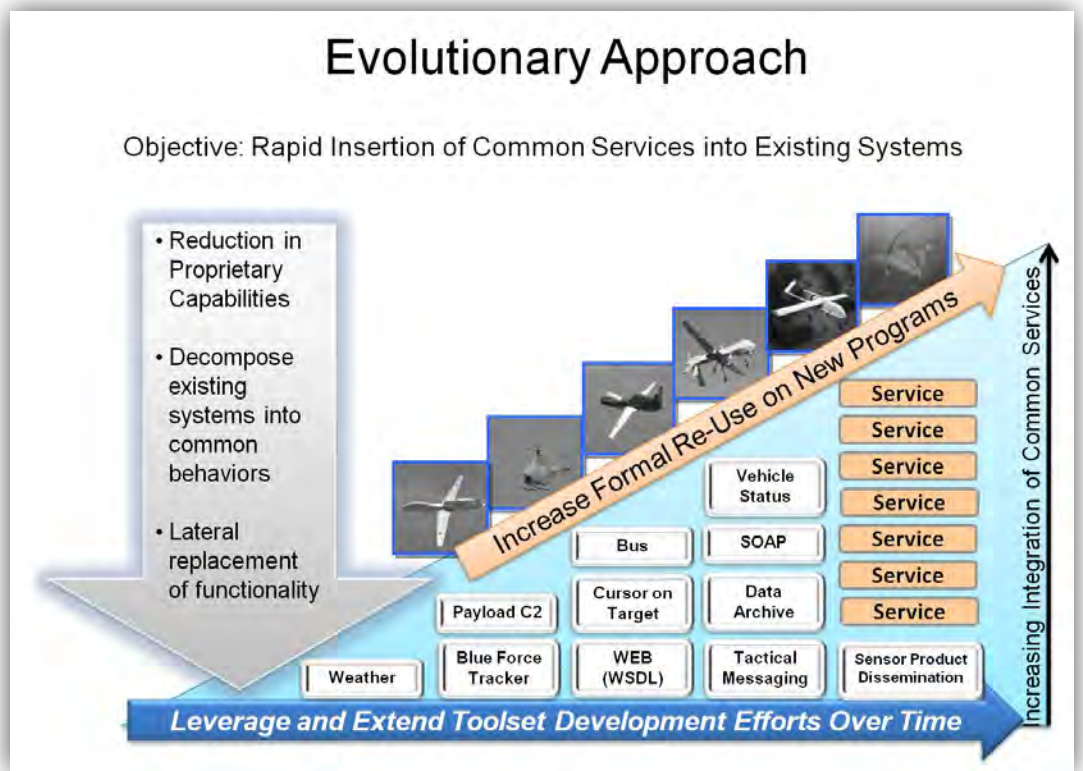


Figure 9. OA Migration Approach.

Quantifiable progress toward migration has already been achieved. The USAF Advanced Cockpit Block 50 (under development by General Atomics) has adopted UCS services and a common data bus. The July 2010 Block 50 implementation of takeoff, flight, payload C2, and landing utilized UCS-based software in a simulated flight environment demonstrated the architecture's utility. Additionally, Northrop Grumman has now agreed to tie its product lines into a common, open product line, with a joint mission-planning-mission-control system document signed by Northrop Grumman executives for synergy and collaboration between Broad Area Maritime Surveillance (BAMS) and Global Hawk unmanned systems. Advanced Explosive Ordnance Robotic System (AEODRS), utilizing an OA approach for hardware and software, is adopting SAE JAUS for messaging and is also developing interoperability profiles to ensure common system functionality descriptions, architectures, and data models. AEODRS is developing three classes of vehicles (dismounted operations, tactical operations, and base/infrastructure operations) with a common architecture and capability modules across the FoS. The AEODRS architecture defines the logical, mechanical, and electrical interfaces for the FoS. The AEODRS is entering Milestone B, and the development of increment 1 (dismounted operations) is now starting.

In addressing interoperability for ground systems, Robotic Systems Joint Project Office (RS-JPO) is utilizing SAE JAUS for messaging (with custom extensions as necessary) and primarily focusing on communications, payloads, power, architecture, and controller. Progress has already been made, with a modeling and simulation demonstration and an Input/Output (IO) Specification Build V1 planned for 2012.

2815 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

4.6 Summary

We can no longer afford to acquire independent, proprietary unmanned systems that do not leverage interoperability. The lines in the battlespace are blurring, and the need to share information, sensors, payloads, and platforms is real. The fiscal battlespace is also blurring, and vendors must shift strategies to adhere to standards, drive toward OAs, reuse software, and develop robust repositories. The goal is to provide more capable unmanned systems to the warfighter on time, and interoperability will ultimately play a large role in this effort by enabling the composition of novel systems capabilities on a faster timescale. Figure 10 depicts an interoperability path for the future as industry and DoD strive to become more efficient.

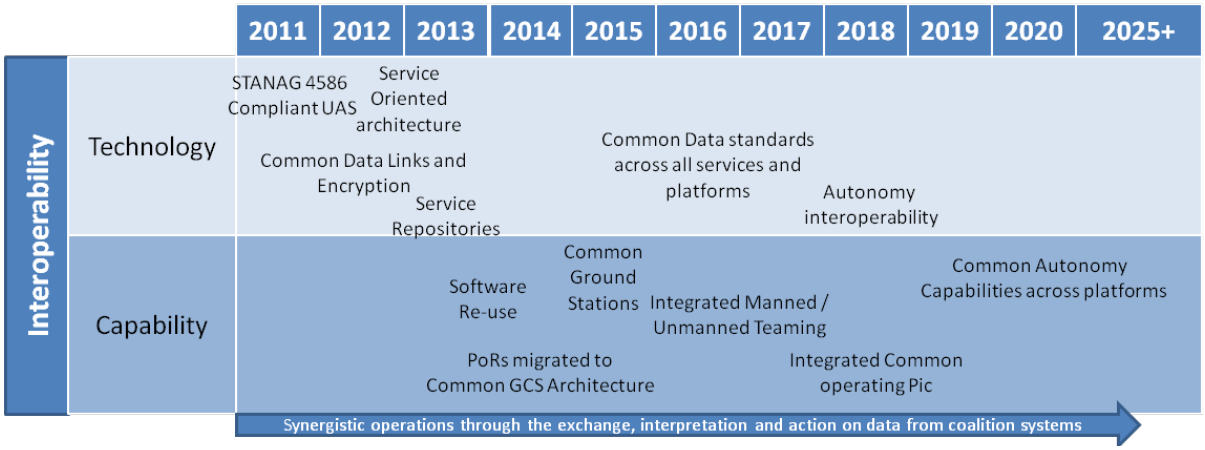

Figure 10. Interoperability Roadmap.

2816 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

5 AUTONOMY

Dramatic progress in supporting technologies suggests that unprecedented levels of autonomy can be introduced into current and future unmanned systems. This advancement could presage dramatic changes in military capability and force composition comparable to the introduction of "net-centricity." DoD must understand and prepare to take maximum practical advantage of advances in this area.[12]

5.1 Functional Description

Automatic systems are fully preprogrammed and act repeatedly and independently of external influence or control. An automatic system can be described as self-steering or self-regulating and is able to follow an externally given path while compensating for small deviations caused by external disturbances. However, the automatic system is not able to define the path according to some given goal or to choose the goal dictating its path.

By contrast, autonomous systems are self-directed toward a goal in that they do not require outside control, but rather are governed by laws and strategies that direct their behavior. Initially, these control algorithms are created and tested by teams of human operators and software developers. However, if machine learning is utilized, autonomous systems can develop modified strategies for themselves by which they select their behavior. An autonomous system is self-directed by choosing the behavior it follows to reach a human-directed goal. Various levels of autonomy in any system guide how much and how often humans need to interact or intervene with the autonomous system, and these levels will be discussed shortly. In addition, autonomous systems may even optimize behavior in a goal-directed manner in unforeseen situations (i.e., in a given situation, the autonomous system finds the optimal solution).

The special feature of an autonomous system is its ability to be goal-directed in unpredictable situations. This ability is a significant improvement in capability compared to the capabilities of automatic systems. An autonomous system is able to make a decision based on a set of rules and/or limitations. It is able to determine what information is important in making a decision. It is capable of a higher level of performance compared to the performance of a system operating in a predetermined manner.[13]

5.2 Today's State

In 2010, the USAF released the results of a year-long study highlighting the need for increased autonomy in modern weapon systems, especially given the rapid introduction of UAS. This study, "Technology Horizons," identified the need for greater system autonomy as the "*single greatest theme*" for future USAF S&T investments. The study cited the potential for increased autonomy to improve effectiveness through reduced decision cycle time while also enabling manpower efficiencies and cost reductions.

[12] USD AT&L *Memo to Chairman, Defense Science Board, Subj Terms of Reference*, 29 March 2010.
[13] NATO Industrial Advisory Group, Study Group 75, Annex C - Autonomous Operations, 2004.

2817 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Autonomous capabilities have been enabled by advances in computer science (digital and analog), artificial intelligence, cognitive and behavioral sciences, machine training and learning, and communication technologies. In order to achieve operational acceptance and trust of these autonomous capabilities in the highly dynamic unmanned system environment, improvement is essential in advanced algorithms that provide robust decision-making capabilities (such as machine reasoning and intelligence); automated integration of highly disparate information; and the computational construct to handle data sets with imprecision, incompleteness, contradiction, and uncertainty.

In response to CCDR needs, the USAF has aggressively expanded UAS capabilities to a target of 65 combat air patrols (CAPs). According to the USAF, 1750 pilots from the Total Force (Active, Guard, and Reserve) are required to maintain these CAPs, which operate around the clock. This increasing manpower requirement is occurring at a time when constrained budgets are limiting growth in Service manpower authorizations. This challenge is not limited to the USAF, but is facing all the military Services. Today's unmanned systems require significant human interaction to operate. As these systems continue to demonstrate their military utility, exploit greater quantities of intelligence, and are fielded in greater numbers, the demand for manpower will continue to grow. The appropriate application of autonomy is a key element in reducing this burden.

> Our Program Managers should be scrutinizing every element of program cost, assessing whether each element can be reduced relative to the year before, challenging learning curves, dissecting overheads and indirect costs, and targeting cost reduction with profit incentive—in short, executing to what the program should cost.
>
> *–Under Secretary of Defense Memorandum for Acquisition Professionals, Better Buying Power, September 2010*

5.3 Problem Statement

The increased manpower to operate unmanned systems is adding stress to the overall workload of the armed forces. This stress highlights the need to transition to a more autonomous, modern system of warfare. The USAF Chief of Staff General Norton Schwartz emphasized the need for more automation in the following statement:[14]

> [The trend] cannot continue indefinitely. There is a place for automation here that reduces the manpower requirement, both to operate and to process the backend data stream.
>
> *– Gen Norton Schwartz, Air Force Chief of Staff*

[14] Fontaine, Scott, "Schwartz outlines possible future changes," *Air Force Times*, 30 August 2010.

2818 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

For unmanned systems to fully realize their potential, they must be able to achieve a highly autonomous state of behavior and be able to interact with their surroundings. This advancement will require an ability to understand and adapt to their environment, and an ability to collaborate with other autonomous systems, along with the development of new verification and validation (V&V) techniques to prove the new technology does what it should. Each of these topics is discussed in more detail below. Advances in autonomy at the system level must proceed with awareness of potential disadvantages and vigilance for unintended consequences, which may include diminished command over parts of the forces structure. Every operation includes rules of engagement, air tasking order (ATO)/special instructions (SPINS), and options of dynamic changes of command direction; and intent must not be traded off. The ability to respond to the unexpected cannot be diminished. For example, dealing with volcanic ash in the atmosphere cannot be reliably predicted at the beginning of an eruption. The ability to respond and avoid affected airspace is an example of a condition that may be difficult for autonomy to address. Implementing autonomy can lead to a loss of human attention to vital oversight in matters having potentially dangerous or lethal consequences. Caution must be used at the system-of-systems level, and constraints applied in some operations in order to allow autonomy in others. Finally, surrendering decision trust to a software-based and self-learning design outside the context of specific operations is a matter of high rigor, and must be examined in the context of organizational-unit and theater CONOPS.

5.4 Way Ahead

Significant advances have been made in autonomy, but many challenges still exist. For relatively static environments and undemanding missions and objectives, rule-based autonomous systems can be highly effective. However, most DoD environments and mission tasks dictate that unmanned systems operate in complex and uncertain environments as well as possess the ability to interact and collaborate with human operators and human teammates. Additionally, autonomous systems need the capability to interact and work together with other autonomous systems, to adapt to and learn from changes in the environment and missions, and to do so safely and reliably. One goal of automation is to leap forward in capabilities using human augmentation. Automated assistance of whatever kind does not simply enhance our ability to perform the task: it changes the nature of the task itself.[15]

5.4.1 Transcending to Higher Levels of Autonomy

Autonomy reduces the human workload required to operate systems, enables the optimization of the human role in the system, and allows human decision making to focus on points where it is most needed. These benefits can further result in manpower efficiencies and cost savings as well as greater speed in decision making. Autonomy can also enable operations beyond the reach of external control or where such control is extremely limited (such as in caves, under water, or in areas with enemy jamming or degraded communications). Advances in autonomy will further increase operational capability, manpower efficiencies, and cost savings.

[15] Norman, D. A., "How might people interact with agents?" *Software Agents*, J. M. Bradshaw, Ed. Cambridge, MA: The AAAI Press/The MIT Press, 1997, pp. 49–55.

2819 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> … the ability to understand and control future costs from a program's inception is critical to achieving affordability requirements.
>
> *–Under Secretary of Defense Memorandum for Acquisition Professionals, Better Buying Power, September 2010*

While reduced reliance on human operators and analysts is the goal of autonomy, one of the major challenges is how to maintain and facilitate interactions with the operator and other human agents. An alternative statement of the goal of autonomy is to allow the human operator to "work the mission" rather than "work the system." In other words, autonomy must be developed to support natural modes of interaction with the operator. These decision-making systems must be cognitively compatible with humans in order to share information states and to allow the operator and the autonomous system to interact efficiently and effectively. The level of autonomy should dynamically adjust based on workload and the perceived intent of the operator. Common terms used for this concept are *sliding autonomy* or *flexible autonomy*. The goal is not about designing a better interface, but rather about designing the entire autonomous system to support the role of the warfighter and ensure trust in the autonomy algorithms and the system itself. Table 3 contains the most commonly referenced description of the levels of autonomy that takes into account the interaction between human control and the machine motions.

Table 3. Four Levels of Autonomy

Level	Name	Description
1	Human Operated	A human operator makes all decisions. The system has no autonomous control of its environment although it may have information-only responses to sensed data.
2	Human Delegated	The vehicle can perform many functions independently of human control when delegated to do so. This level encompasses automatic controls, engine controls, and other low-level automation that must be activated or deactivated by human input and must act in mutual exclusion of human operation.
3	Human Supervised	The system can perform a wide variety of activities when given top-level permissions or direction by a human. Both the human and the system can initiate behaviors based on sensed data, but the system can do so only if within the scope of its currently directed tasks.
4	Fully Autonomous	The system receives goals from humans and translates them into tasks to be performed without human interaction. A human could still enter the loop in an emergency or change the goals, although in practice there may be significant time delays before human intervention occurs.

2820 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> The single greatest theme to emerge from "Technology Horizons" is the need, opportunity, and potential to dramatically advance technologies that can allow the Air Force to gain the capability increases, manpower efficiencies, and cost reductions available through far greater use of autonomous systems in essentially all aspects of Air Force operations. Increased use of autonomy — not only in the number of systems and processes to which autonomous control and reasoning can be applied but especially in the degree of autonomy that is reflected in these — can provide the Air Force with potentially enormous increases in its capabilities, and if implemented correctly can do so in ways that enable manpower efficiencies and cost reductions.
>
> *– USAF Report on Technology Horizons: A Vision for Air Force Science and Technology During 2010-2030, 15 May 2010*

5.4.2 Ability to Understand and Adapt to the Environment

To operate in complex and uncertain environments, the autonomous system must be able to sense and understand the environment. This capability implies that the autonomous system must be able to create a model of its surrounding world by conducting multisensor data fusion (MDF) and converting these data into meaningful information that supports a variety of decision-making processes. The perception system must be able to perceive and infer the state of the environment from limited information and be able to assess the intent of other agents in the environment. This understanding is needed to provide future autonomous systems with the flexibility and adaptability for planning and executing missions in a complex, dynamic world.

Although such capabilities are not currently available, recent advancements in computational intelligence (especially neuro-fuzzy systems), neuroscience, and cognition science may lead to the implementation of some of the most critical functionalities of heterogeneous, sensor net-based MDF systems. The following developments will help advance these types of processing capabilities:

1. **Reconfigurability of sensor weighting:** When a heterogeneous sensor net is used for an MDF system, each sensor has a different weight for different applications. As an example, regardless of whether a dissimilar MDF methodology is used to identify an object, an image sensor has much higher weight than radar. On the other hand, when an MDF methodology is used to measure a distance from the sensor to an object, a rangefinder or radar has a much higher weight than an image sensor.
2. **Adaptability of malfunctioning sensors and/or misleading data:** Even if an MDF methodology is used to identify an object, an image sensor cannot perform if it is faced to the sun. Data from the image sensors will either be saturated or need to be calibrated. Additionally, the image sensor data needs to be continuous calibrated if the weather is cloudy and changing because the measured data will be different based on shadows and shading. Therefore, the environment of a heterogeneous sensor net is a key parameter to be considered for design and implementation of an MDF system.

2821 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

3. **Intelligent and adaptive heterogeneous data association:** Heterogeneous, sensor net-based MDF systems must process different data simultaneously, such as one-dimensional radar signals, two-dimensional imaging sensor data, etc. As the combination of heterogeneous sensors change, the data combination is changed. Therefore, adaptive data association must be performed before conducting MDF and data input to the decision-making module.
4. **Scalability and resource optimization of self-reconfigurable fusion clusters:** The limiting factor of an MDF system is the scalability of self-reconfiguring the fusion cluster to adapt to a changing battlefield and/or the malfunction of one or more sensors. As the number of sensors used for a sensor net increases, the combinatorial number of reconfigurations exponentially increases. To manage such complexity, the MDF system will require a highly intelligent, fully autonomous, and extremely versatile reconfigurable algorithm, including sensor resource management and optimization. Great progress has been made in sensor management algorithms and cross-cued sensor systems, but true optimization is an elusive goal that is currently unavailable. Such capability can be obtained only from intelligent computing technology, which is currently in its infancy.

While robustness in adaptability to environmental change is necessary, the future need is to be able to adapt and learn from the operational environment because every possible contingency cannot be programmed *a priori*. This adaptation must happen fast enough to provide benefits within the adversary's decision loop, and the autonomy should be constructed so that these lessons can be shared with other autonomous systems that have not yet encountered that situation. Yet even in a hostile, dynamic, unstructured, and uncertain environment, this learning must not adversely affect safety, reliability, or the ability to collaborate with the operator or other autonomous systems. The flexibility required of autonomous systems in dynamic, unstructured environments complicates the predictability needed for U.S. commanders to "trust" the autonomy.

"Trust" will be established through robust operational T&E along with safeties and safeguards to ensure appropriate behavior. Complex autonomous systems must be subject to rigorous "red team" analysis in order to evaluate the full range of behaviors that might emerge in environments that simulate real-world conditions. Safeties and safeguards are also required to mitigate the consequences of failures. Because artificial systems lack the human ability to step outside a problem and independently reevaluate a novel situation based on commander's intent, algorithms that are extremely proficient at finding optimal solutions for specific problems may fail, and fail badly, when faced with situations other than the ones for which they were programmed. Robust safeties and control measures will be required for commanders to trust that autonomous systems will not behave in a manner other than what is intended on the battlefield.

5.4.3 Enabling Greater Autonomy in TPED Processes

In addition to C2 processes, traditional TPED processes offer huge opportunities for reducing the degree of human involvement. Near-term developments could introduce a greater degree of automation, ultimately evolving to more autonomous systems. Current TPED processes are manpower intensive. In today's combat environment, most full-motion video (FMV) and still imagery is monitored and used in real time, but then stored without being fully analyzed to exploit all information about the enemy. This challenge is not unique to the unmanned

2822 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

environment, but it has been exacerbated by the large numbers of ISR-capable, long-endurance unmanned systems being fielded. These systems are collecting great quantities of information and overwhelming current TPED processes. Near-term steps might include implementation of change detection and automatic target recognition software to enable automated cueing that identifies and calls attention to potential threats. Applications of face recognition software could enable high-fidelity FMV to identify individuals of interest. Increased automation in communications intelligence sensors has the potential to identify key words and even specific voices to rapidly alert operators to targets of interest. Ultimately, automated cross-cueing of different sensor types in a networked environment could enable greater autonomy in tasking systems and their sensors to identify and track threats more rapidly.

Increased processing power and information storage capacities also have the potential to change how unmanned systems operate. For example, many current UAS transmit ISR data that is processed and exploited in ground stations. If more processing and exploitation processes can be accomplished onboard a UAS (like the automatic target recognition or communications intelligence examples discussed above), the system can disseminate actionable intelligence for immediate use and reduce bandwidth requirements. FMV ISR, for example, uses roughly an order of magnitude more bandwidth than the C2 data for a UA. By accomplishing more of the TPED process onboard the unmanned system, the link bandwidth can then be focused on transmitting only what's needed, and the overall bandwidth requirements can be reduced.

> Today an analyst sits there and stares at Death TV for hours on end trying to find the single target or see something move or see something do something that makes it a valid target. It is just a waste of manpower. It is inefficient!
>
> *– Gen James Cartwright, Vice Chairman of the Joint Chiefs of Staff, during remarks to the U.S. Geospatial Intelligence Foundation on 4 Nov 2010*

5.4.4 Ability to Collaborate with Other Autonomous Systems

In addition to understanding the environment, unmanned systems must also possess the ability to collaborate through the sharing of information and deconfliction of tasking. Collaborative autonomy is an extension of autonomy that enables a team of unmanned systems to coordinate their activities to achieve common goals without human oversight. This trend in autonomy will continue to reduce the human role in the system. Autonomously coordinated unmanned systems may be capable of faster, more synchronized fire and maneuver than would be possible with remotely controlled assets. This trend will lead to a shift toward strategic decision making for a team of vehicles and away from direct control of any single vehicle.

2823 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The ability to collaborate is one of the keys to reducing force structure requirements. The collaborative autonomy that is developed must be scalable to both larger numbers of heterogeneous systems as well as increased mission and environment complexity. Collaborative autonomy must be able to adapt to the air, ground, and maritime traffic environment and to changes in team members, operators, and the operational environment.

5.4.5 Development of New Approaches to Verification and Validation (V&V)

To ensure the safety and reliability of autonomous systems and to fully realize the benefits of these systems, new approaches to V&V are required. V&V is the process of checking that a product, service, or system meets specifications and that it fulfills its intended purpose. These components are critical in a quality management system such as ISO 9000. Today's V&V processes will be severely stressed due to the growth in the amount and complexity of software to be evaluated. They utilize existing industry standards for software certification that are in place for manned systems (e.g., DO-178B). Without new V&V processes, such as the use of trust audit trails for autonomy, the result will be either extreme cost growth or limitations on fielded capabilities.

Efforts leading to advancements in computational intelligence as well as the appropriate V&V processes are essential. Enhanced V&V technologies would provide both near-term cost reduction and enhanced capabilities for current autonomous systems and would enable otherwise cost-prohibitive capabilities in the future. New autonomous system test and analysis capabilities are also required to assess intelligent single-vehicle and group behaviors. These technological enhancements and policy actions would lead to more effective development, testing, and operations of current and future autonomous systems.

5.4.6 Policy Guidelines to Ensure Safe Operation

Additional measures, beyond V&V, will be required to ensure safe operation of autonomous systems. No V&V process can guarantee 100% error-free operation of complex systems. As software complexity increases, predicting the precise behavior of autonomous systems in real-world environments will be increasingly difficult. Policy guidelines are necessary in order to ensure that if failures or malfunctions occur, or if an unmanned system encounters an unanticipated situation, the system continues to operate appropriately.

Policy guidelines will especially be necessary for autonomous systems that involve the application of force. Current armed, unmanned systems deploy lethal force only in a fully human-operated context (level 1) for engagement decisions. For these systems, the decisions both to employ force and to choose which specific target to engage are made by a human. The United States does operate defensive systems for manned ships and installations that have human-supervised autonomous modes (level 3), and has operated these systems for decades. For the foreseeable future, decisions over the use of force and the choice of which individual targets to engage with lethal force will be retained under human control in unmanned systems.

5.5 Summary

Technological advances in autonomy are critical as the need to field greater numbers of unmanned systems stresses the limited number of available operators. Challenges in the area of

2824 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

autonomy address not only functionality, but also transparency to the operator, safety, and reliability. Figure 11 provides a vision into the future of the autonomy advances that are required to maintain an affordable force structure and confidently operate unmanned systems in an increasingly complex environment. Initially, autonomy will improve the safe operations of unmanned systems within the increasingly complex environment of military operations as well as reduce operator workload associated with mundane and noncritical processes. Ultimately, autonomy will increase warfighter effectiveness by enhancing unmanned systems capabilities and expanding their capacity to effect results in the battlespace.

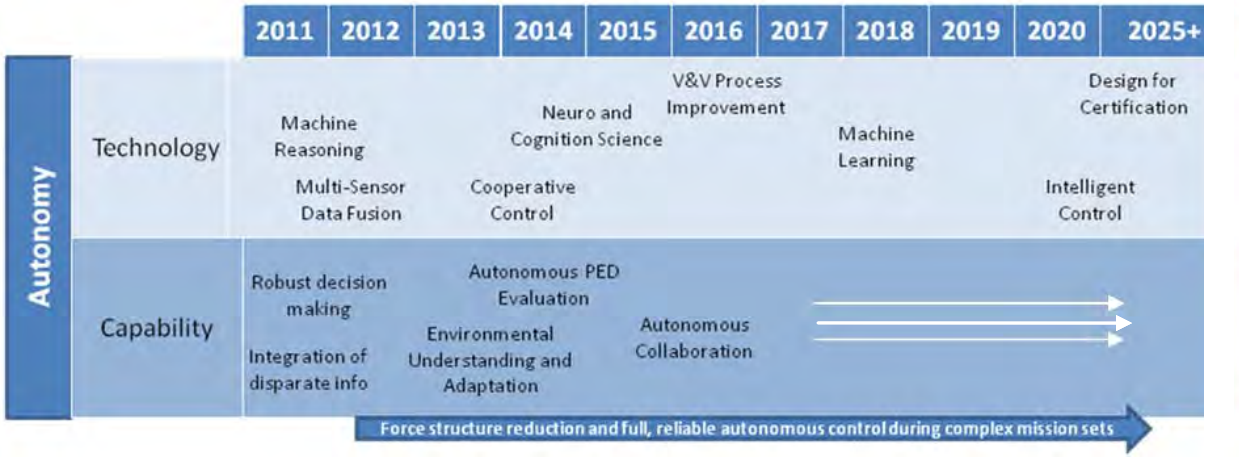

Figure 11. Autonomy Roadmap.

2825 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

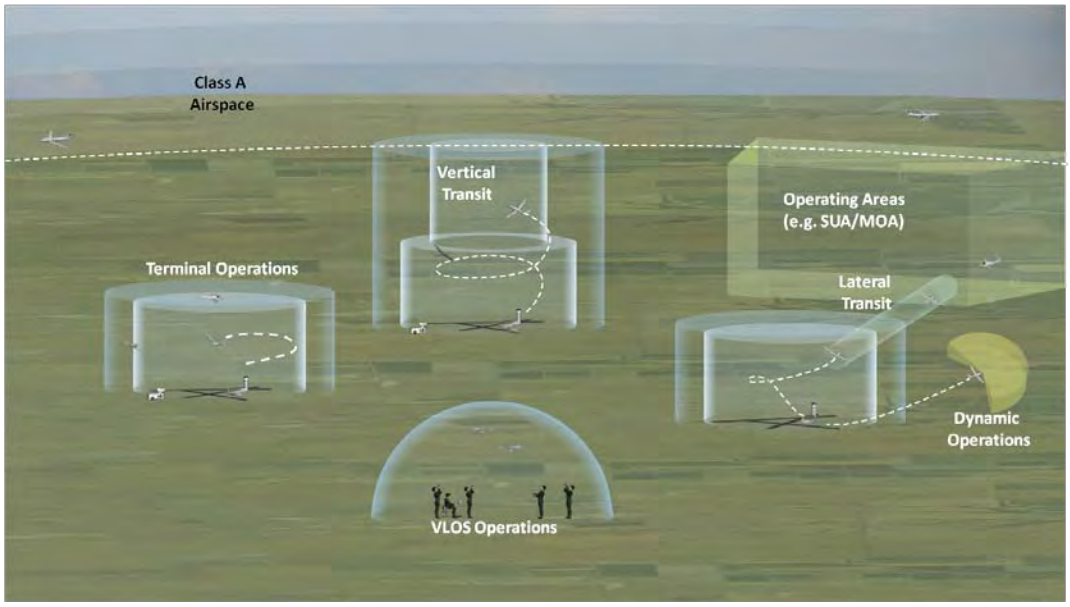
6 AIRSPACE INTEGRATION (AI)

6.1 Functional Description

Over the past several years, UAS have become a transformational force multiplier for DoD. The numbers and roles of UAS have expanded dramatically to meet mission demands, and operational commanders have come to rely upon robust and persistent ISR support from unmanned platforms executing their core missions against hostile forces. DoD UAS require routine NAS access in order to execute operational, training, and support missions and to support broader military and civil demands. UA will not achieve their full potential military utility to do what manned aircraft do unless they can go where manned aircraft go with the same freedom of navigation, responsiveness, and flexibility. Military aviation is a major contributor to the virtue of maneuver for our forces in warfare.

While the force structure continues to grow, the ability to integrate UAS into the NAS has not kept pace. Current access for UAS is greatly limited primarily due to FAA regulatory compliance issues that govern UAS operations in the NAS. DoD UAS operations conducted outside of restricted, warning, and prohibited areas are authorized only under a (temporary) COA from the FAA. Similar issues need to be resolved for access to international and foreign national airspace.

The *DoD UAS Airspace Integration Plan, March, 2011* provides a more comprehensive discussion on the topic of AI. In this plan, DoD provides an incremental approach strategy to provide DoD UAS access to a given operations profile that leads to a full dynamic operations solution. This methodology recognizes that DoD requires access to differing classes and types of airspace as soon as possible and that routine dynamic operations will likely take several years to implement. Figure 12 depicts the six access profiles.



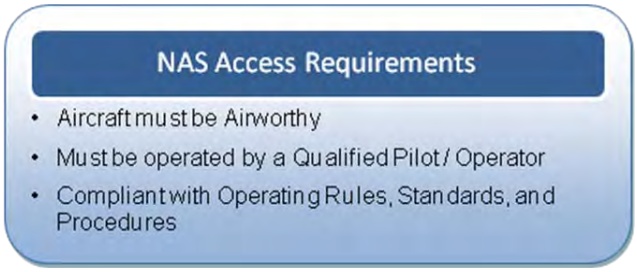


Figure 12. Operational View.

2826 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

6.1.1 Vision

DoD's vision is to ensure UAS have routine access to the appropriate airspace required to meet mission needs. For military operations, UAS will operate with manned aircraft using CONOPS that make manned or unmanned aircraft distinctions transparent to air traffic services (ATS) authorities and airspace regulators. Having robust UAS AI capabilities for all classes of U.S. airspace is fundamental to flexible worldwide UAS deployment.

> … it is vital for the Department of Defense and the Federal Aviation Administration to collaborate closely to achieve progress in gaining access for unmanned aerial systems to the National Airspace System to support military requirements.
>
> *– 110th Congress, NDAA for FY09, Sect 1039*

6.1.2 Precepts

The *2010 DoD Airspace Integration Plan* outlines DoD's approach, which is summarized by four overarching precepts (see right). The U.S. military will use its vast experience to develop the safest, most capable UAS fleet possible. We will strive for maximum compliance with existing regulatory guidance and inform regulatory processes when changes are needed. DoD will fully leverage statutory authorities to design, test, and ultimately certify its UAS in compliance with applicable standards, regulations, and orders. The regulatory and policy changes may be broad in scope to affect multiple Military Departments and Combatant Commands (CCDRs); therefore, UAS AI activities should make every effort to be coordinated prior to engaging with FAA or other external agencies.

6.2 Today's State

In order for any military aircraft — manned or unmanned — to fly routinely in domestic and international airspace, three foundational requirements must be met. These three requirements are essential and form the foundation for UAS AI. Title 10 of the United States Code (USC) is the legal underpinning for the roles, missions, and organization of DoD and provides authority for the military departments to organize, train, and equip U.S. forces to fulfill the core duties for national defense. Consistent with this statutory authority and longstanding practice and reinforced by interagency agreements, DoD is responsible for establishing airworthiness and

2827 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

pilot training/qualification requirements for the military and ensuring rigorous military standards are satisfied.[16] The third and most complex requirement, regulatory compliance, encompasses both internal military department regulations and external FAA and International Civil Aviation Organization (ICAO) flight regulations.

6.2.1 Airworthiness

Airworthiness is a basic requirement for any aircraft system, manned or unmanned, to enter the NAS. The primary guidance for DoD airworthiness certification is found in MIL-HDBK-516B, *Airworthiness Certification Criteria.* This document defines airworthiness as "*the ability of an aircraft system/vehicle to safely attain, sustain and terminate flight in accordance with an approved usage and limitation.*"[17] Airworthiness certification ensures that DoD aircraft systems are designed, manufactured, and maintained to enable safe flight. Certification criteria, standards, and methods of compliance establish a minimum set of design and performance requirements for safely flying a given category and class of aircraft. The DoD is expanding current military airworthiness guidance to include criteria that address those component and system attributes that are unique to UA. UAS-unique standards derived from NATO STANAGs (e.g., 4671[18], 4705, and 4703) will be reviewed and incorporated as appropriate.

6.2.2 Pilot/Operator Qualification

The DoD determines where and how it will operate its aircraft, and each Military Department creates the qualification training programs necessary to safely accomplish the missions of that aircraft or weapon system. The standards to train and qualify pilots/operators of UAS will remain under the authority of the Military Departments and appropriate CCDRs. UAS pilot/operator training requires a different skill set from the set needed for flying manned aircraft due to differences such as the means of takeoff, cruising, and landing by visual remote, aided visual, or fully autonomous methods. Therefore, the Military Departments and CCDRs must apply the minimum training standards outlined in CJCSI 3255.01 to their respective training programs to ensure the requisite knowledge, skills, and abilities are addressed appropriately.

[16] Title 10 provisions relating to service authority to organize, train, and equip include 10 U.S.C. Sec. 8062 (Air Force), 10 U.S.C. Sec. 3062 (Army), 10 U.S.C. Sec. 5062 (Navy), and 10 U.S.C. Sec. 5063 (Marine Corps). Multiple service instructions address airworthiness standards, e.g., Air Force Instruction 62-601, dated 11 June 2010.
[17] MIL-HDBK-516B with change 1, *Airworthiness Certification Criteria*, 29 February 2008.
[18] NATO STANAG 4671, Unmanned Aerial Vehicle Systems Air Worthiness Requirements (USAR).

2828 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

6.2.3 Regulatory Compliance

The Military Departments have a robust process for establishing manned aircraft flight standards and procedures. However, the current ambiguity and lack of definition in national and international regulatory guidelines and standards for UAS make it difficult to know, with consistency or certainty, whether UAS can comply. In fact, some current UAS may already be operating at appropriate levels of safety; however, until the necessary UAS-specific standards, regulations, and agreed-upon compliance methodologies are defined, establishing regulatory compliance for more routine operations is difficult. In the meantime, UAS operations within the NAS are treated as exceptions through the COA process.

While many requirements can be met through the use of existing manned aircraft, many missions are more efficiently and safely accomplished by using unmanned platforms. Technology advancements may be able to help resolve regulatory compliance issues for UA (particularly Title 14 of the U.S. Code of Federal Regulations (14 CFR) 91.113 containing the see and avoid provision); however, the level and complexity of technology required to resolve today's regulatory compliance issues will negatively affect system affordability.

6.3 Problem Statement

The number of UAS in the DoD inventory is growing rapidly. The increase in numbers, as well as the expanding roles of UAS, has created a strong demand for access to national and international airspace and has quickly exceeded the current airspace available for military operations.

6.4 Way Ahead

6.4.1 Methodology

DoD's UAS NAS access methodology includes the array of UAS platform capabilities, required airspace, technology improvement, and implementation activities/products required to attain routine operations within the NAS. This methodology uses an incremental approach to provide DoD UAS access to a given operations profile that leads to a full dynamic operations solution (see Figure 13). This methodology recognizes that DoD requires access to differing classes and types of airspace as soon as possible and that routine dynamic operations will likely take several years to implement.

The profiles, as outlined in an operational view (Figure 12) and DoD's AI Plan, may be used individually to access specific local airspace or integrated together to satisfy additional airspace requirements. Visual LOS operations establish a means to conduct UAS operations in Visual Flight Rules conditions. The terminal area profile is intended to facilitate UAS operations in a confined volume of airspace, such as Class D airspace or near restricted airspace. UAS operating areas, such as special use airspace (e.g., restricted area, or military operations area (MOA)), can be accessed either by flying through a lateral corridor (through Class E) or by vertically ascending to Class A airspace and flying across. While operating areas are limited to restricted or warning areas, MOAs are desirable because they offer a wide variety of airspace spanning 43 states to provide a robust, nationwide UAS training capability without the creation of new airspace.

2829 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

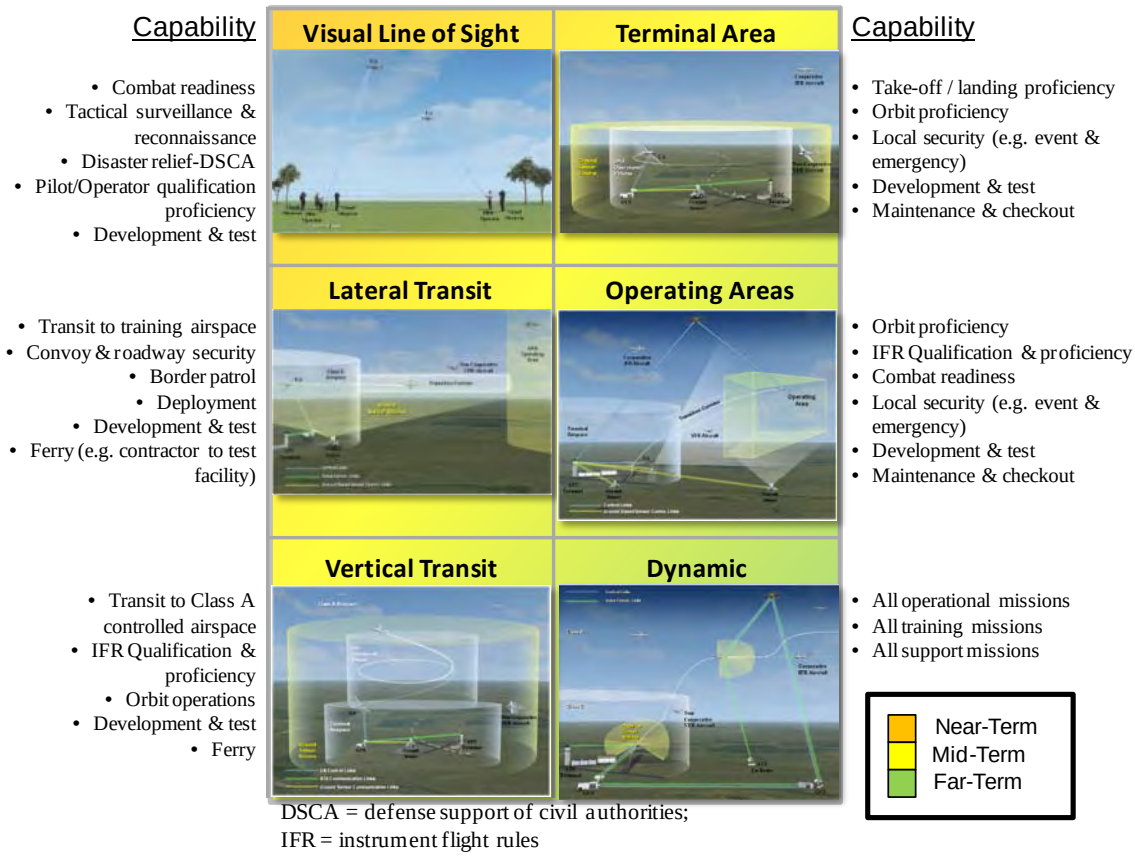

Figure 13. Incremental Approach to Regulatory Compliance.

Plans and programs to enable UAS operations within a profile will be evaluated for joint applicability and NAS access utility. For example, because most of the required near-term airspace for DoD UAS will be in Class D, E, and G, DoD intends to focus much of its near-term resources on addressing this major need.

6.4.2 Policy

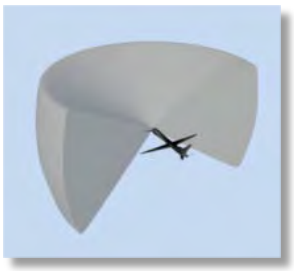
Policy agreements can maintain the safety of the NAS while also allowing certain requirements to be fulfilled. In 2007, DoD and FAA signed a Memorandum of Agreement (MoA) allowing limited UAS operations for small UAS below 1200 ft above ground level (AGL) and UAS within DoD-controlled, non-joint-use Class D airspace. The 2007 MoA will be updated periodically, as needed, to allow DoD to incrementally increase access to the NAS. For example, the small UAS special federal aviation regulation is expected to be complete in 2013, but DoD can immediately leverage this work by seeking to incorporate many of the recommendations into an updated DoD-FAA MoA.

2830 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The Policy Board on Federal Aviation (PBFA) serves as the DoD liaison with the FAA on federal air traffic control and airspace management. The board provides policy and planning guidance to ensure the Military Departments have sufficient airspace to fulfill requirements. With support from OSD and the Military Departments, the board is working with FAA to update the 2007 MoA.

Where broader issues involve other agencies, the DoD participates in the UAS Executive Committee (ExCom). The ExCom acts as a focal point for senior leaders from FAA, DoD, DHS, and National Aeronautics and Space Administration (NASA) to meet periodically to resolve any policy and procedural disputes and to identify solutions to the integration of UAS into the NAS. The ExCom has established a working group to address COA issues, published a plan to Congress in October 2010, and continues to address specific issues such as collecting and sharing UAS safety data.

6.4.3 Technology



Current UAS are built to different specifications for different purposes; therefore, showing individually that each system is safe for flight in the NAS can be complicated, time consuming, and costly. Routine access cannot happen until DoD and FAA agree to an acceptable level of safety for UAS, and the appropriate standards are developed to meet that threshold. With developed standards, UA will be operationally treated as manned systems, and such treatment will improve interoperability with other systems, cost savings, and development transparency.

Until those necessary UAS-specific standards are established, requirements will be dependent on the individual system and intended flight environment (access profiles). Each system's mission requirements will drive the selection of sense and avoid (SAA) solutions and process for implementation. Ground-based sense and avoid (GBSAA) can provide an initial means to maintain aircraft separation requirements for multiple profiles, while improvements to sensor and automation technology will continue to improve an airborne SAA (ABSAA) solution.

GBSAA efforts are focused on developing methods to provide aircraft separation within a prescribed volume of airspace using a ground-based system that includes sensors, displays, communications, and software. GBSAA solutions will incrementally relieve restrictions on existing COAs and facilitate UAS training and operations in the NAS. This effort is establishing requirements, gathering data, performing modeling and simulation, testing and verifying collected data, and obtaining airworthiness approvals, as appropriate. GBSAA can particularly benefit smaller UAS where other SAA solutions are cost prohibitive.

2831 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ABSAA efforts are focused on developing onboard capability to perform both self-separation and collision avoidance that ensure an appropriate level of safety. Current programs have phased validation schedules for due regard, en-route/Class A, and divert/ Class E/G operations as technology innovation and integration allow. GBSAA and ABSAA may be applied as a single or combined solution to some access profiles to maximize safety and/or reduce operational costs.

6.4.4 CONOPS Development

The DoD is developing an AI CONOPS to provide a framework for common UAS practices, procedures, and flight standards in NAS and international airspace. It is intended to standardize UAS access methodologies and procedures, implement appropriate methods for compliance with see-and-avoid requirements, and inform development of an UAS AI Initial Capabilities Document (ICD). It will establish a standard suite of lost-link, lost-communications, and lost-SAA procedures for DoD UAS in all phases of flight. These procedures will help define methods for notification and the appropriate action to either regain link or recover/divert the UA. The CONOPS also provides the operational and procedural construct to employ the access profiles at bases across the United States and to inform the process of basing UAS in locations outside the continental United States (OCONUS).

6.4.5 Requirements Development

The CONOPS, along with the Military Departments' individual location airspace requirements, will feed development of an UAS AI ICD. The UAS AI ICD is intended to identify the financial requirements for UAS integration into the NAS across the United States and OCONUS. As the initial SAA technologies mature through development and validation, they can be applied to the appropriate profiles and documented in the UAS AI ICD. This effort will allow the Military Departments to accurately estimate the costs to operate UAS at any given individual location as needed.

> … limited access to airspace is having a negative impact on the unmanned aviation community and many regions of the U.S. that are ready to support UAS industry growth.… over the next 15 years more than 23,000 UAS jobs could be created in the U.S. as the result of UAS integration into the NAS.
>
> *– Aerospace Industries Association. (2010). Total Employment: Annual Calendar Years 1990-2009. Available at AIA website: http://www.aia-aerospace.org/assets/stat12.pdf*

6.4.6 Timing of Activities

The DoD is focusing on near-term, mid-term, and far-term activities. This timing allows for immediate improvements in NAS access, while working toward viable long-term solutions.

2832 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Near-term activities address small UAS, DoD-controlled airspace, and operations under COAs**.** Priority is given to initiatives that reduce COA requirements and streamline the FAA approval process. DoD believes significant near-term improvement in UAS NAS access is achievable through COA, policy, and procedural initiatives.
- Mid-term activities address local airfield and transit operations. Where policy and procedures fall short of achieving the long-term objective of routine access, a significant investment in standards and technology development is necessary. Priority is given to developing validated AI requirements and associated standards and to establishing an SAA capability that will provide NAS access through special rules and policy, new procedures, and use of ground-based sensor technology.
- Far-term activities address most UAS missions in any operating location and airspace to include FAA's Next Generation Air Traffic Control System (NextGen). The end state is routine NAS access comparable to manned aircraft for all DoD UAS.

6.5 Summary

DoD UAS have become a critical component of military operations. Many DoD UAS now require rapidly expanded access to the NAS and international civil airspace to support operations, training, testing, and broader governmental functions.

In order for military aircraft to fly routinely in domestic and international airspace, the aircraft must be certified as airworthy, operated by a qualified pilot/operator in the appropriate class(es) of airspace, and comply with applicable regulatory guidance. DoD exercises sole certification authority for its aircraft and pilots/operators, consistent with authority provided in Title 10 of the US Code.

DoD's UAS NAS access methodology uses an incremental approach to provide DoD UAS critical access to a given operations profile prior to implementing a full dynamic operations solution. DoD's immediate focus is gaining near-term mission-critical access while simultaneously working toward far-term routine NAS access. DoD's efforts will have positive affordability effects by championing utilization of UAS within the NAS. This progress will be accomplished through policy and procedural changes as well as technology and standards development and is thoroughly outlined in the AI Plan. The end state is routine NAS access comparable to manned aircraft for all DoD UAS operational, training, and support missions.

Figure 14. UAS NAS Roadmap.

7 COMMUNICATIONS

> "Ongoing operations in Southwest Asia continue to drive the voracious demand for pilots, support personnel and bandwidth above all"
>
> *– Col. J.R. Gear, USAF, speaking at recent C4ISR Journal Conference in Washington.*

7.1 Functional Description

DoD unmanned systems need a process for operational control and mission data distribution, especially for nonautonomous systems. For some ground and maritime systems, these types of exchanges of information can use a cable for the transmission path, but for highly mobile unmanned operations, the exchange is more likely to use signals sent across the electromagnetic spectrum (EMS) or by other means (e.g., acoustical or optical). The EMS is highly regulated at the national[19] and international[20] levels. While numerous over-the-air communication systems have been designed, built, and fielded and have performed reasonably well, others have been fielded in a noncompliant status and have not met difficult operational constraints.

DoD's desire is to operate unmanned systems in theater or within the United States and its possessions so that communication constraints do not adversely affect successful mission execution. Specifically, DoD must significantly improve communication transmission efficiencies; attain better bandwidth efficiencies; increase transmitter and receiver efficiencies; and acquire communications systems that are of less size and weight, require less power, and provide more efficient cooling to operate.

The operational employment of Unmanned Aircraft Systems requires access to a range of SATCOM capabilities. Planning and budgeting for UAS operations must take into account realistic assessments of projected SATCOM bandwidth (both military and commercial) in a range of operational scenarios. Investments in UAS systems must be matched with appropriate investments in the military and commercial SATCOM capabilities that are required to support UAS operations.

7.2 Today's State

The state of unmanned systems communication systems differs greatly among the air, ground, and maritime environments. In supporting operations in OIF, Operation New Dawn (OND), and OEF there has been a large number of new sensors and communication systems installed on various fielded unmanned systems. These have significantly increased the amount of data that has been collected, and that is desired to be sent to local and remote warfighters. To

[19] For the U.S. Government, see the National Telecommunications and Information Administration's *Manual of Regulations and Procedures for Federal Radio Frequency Management*. Washington, DC, January 2008 edition, September 2009 revision (incorporated by reference under 47 CFR 300.1).
[20] International Telecommunication Union (ITU), Radio Regulations, Geneva, Switzerland. 2007 Edition.

2834 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

get the needed data to the remote warfighters, the DoD pays significant funds to several commercial large data transmission companies. Many current unmanned systems have experienced the impact of frequency congestion, interference from systems operating in adjacent frequency bands, and the physical limits associated with the spectrum that has been made available.

The following paragraphs describe the current communication environments by domain.

7.2.1 Unmanned Ground Systems (UGS)

Until recently, most unmanned systems utilized several radios: one for data, one for video, and sometimes one for voice. Because of congestion, frequency competition, and regulatory challenges in several theaters, many of these communication systems were redesigned to operate at higher frequencies. However, use of these higher frequencies reduced the operational effectiveness in dense foliage and urban areas.

7.2.2 Unmanned Aircraft Systems (UAS)

Small, hand-carried and/or hand-launched systems (e.g., the Raven) utilize LOS communications, while large aircraft (e.g., the Predator, Reaper, Gray Eagle, and Global Hawk) utilize both LOS and BLOS communications, the latter generally using satellite communications.

Initial small UAS (< 20 lbs) communication systems utilize industry analog designs, but most now utilize the Army-developed digital data link (DDL) system.[21] The DDL design incorporates aspects of a software-defined radio with the ability to "field-select"[22] the frequency band in which to operate, the channel frequency within that band, the bandwidth of each channel, and the radiated power level.[23] Larger UAS operating LOS incorporate the common data link (CDL) that has been mandated for use in ISR platforms.

7.2.3 Unmanned Maritime Systems (UMS)

There are unique challenges related to UMS: dealing with the air water interface, transmission loss communicating underwater, and negotiating the dynamics of the sea surface. Intermittent communications are the norm in maritime systems and multispectral capabilities are utilized to meet communications requirements. Primary tradeoffs to be considered when evaluating a mode of communication for a USV or UUV that supports dynamic tasking, querying, and data dissemination include data rate, processing capability, range, detectability, and negotiating the maritime environment. These are of particular concern for the ISR and the

[21] Developed by the Army's Natick Soldier Research, Development & Engineering Center. An alternative DDL for small UAS is also being developed that could use a version of CDL. NATO has developed STANAG 4660, Interoperable Command and Control Data Link for Unmanned Systems (IC2DL), which is based on the DDL.
[22] This selection process is not by software but by switches. Moving to software control is being considered during a future upgrade of the DDL.
[23] The USAF Cryptographic Modernization Program Office and the Army developed a prototype encryptor for this DDL.

2835 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ASW missions when communication is desired without exposing either the sender or receiver to possible hostile interception.[24]

7.3 Problem Statement

There are alarming red flags early in this Roadmap's time horizon regarding the amount of data that future UMS sensors will be collecting. How to best deal with that amount of data and distributing the needed information within that data to the right warfighters at the right time will be a major challenge. Left unchecked, sending all that data to local or remote sites will tax current technology and available funding (e.g., COMSAT links). The DoD needs communication technologies and tactics, techniques, and procedures that overcome these limitations and that are agile, robust, redundant, efficient, and affordable. Those needed technologies are discussed throughout Section **7.4 Way Ahead**. However, improved communication transmission technologies alone cannot achieve the necessary capacity. The DoD must pursue a fundamental shift to a future state where we pre-process the collected data, rapidly pass only critical data on to the warfighters, and then store for later retrieval the remaining data that may be needed.

In addition to achieving these technology advances[25], their application in UMS needs to meld with overall DoD wireless network communication concepts, meet national objectives for unmanned systems, and properly address regulatory policies and their limitations. All this needs to be done early in the requirements development process so those advances can be incorporated within future UMS.

In particular, tomorrow's UMS will need to utilize technical strategies which can more efficiently deal with extremely large data sets. In managing this data, better data compression, encryption and processing algorithms need to be employed in preprocessing, transmission and data fusion. These strategies also need to mandate efficient use of the spectrum, reduce frequency use overhead, allow for data security and ensure improved clarity of the available frequency spectrum. To support DoD's goals, communication systems need to support multiple frequency bands, limited bandwidth, variable modulation schemes, error correction, data encryption, and compression. All this support, of course, needs to be done so that no electromagnetic interference (EMI)[26] is caused within those systems or within other nearby spectrum-dependent systems (SDS).

There are numerous challenges to meeting this goal. First, operating a higher density of unmanned systems within relatively small areas creates increased local data rate demands. Second, size, weight, power and cooling (SWaP-C) are limiting factors on many platforms, for both onboard systems and ground/surface control systems. Third, the fidelity of the communication links must be ensured. Fourth, latency associated with digital systems must be reduced, especially for takeoff and landing of large UAS. These challenges will be exacerbated

[24] U.S. Navy Undersea Dominance Roadmap.
[25] These advances need to include government ownership of critical data and intellectual property to ensure the best return on our research investment.
[26] The development of the resulting on-board and ground stations needs to address EMI hardening and the units tested per MILSTD-464A and MILSTD-461F.

2836 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

by an expected decrease in available spectrum available due to an increase in the civil[27] uses of spectrum, an objective within the Federal Communications Commission's (FCC's) National Broadband Plan[28]and directed by the White House[29].The challenges in attaining this goal include developing, procuring, testing, and fielding communication systems that can operate with greater effectiveness, efficiency, and flexibility even in congested and adversarial environments.

Spectrum testing in unmanned systems today involves communications across a global environment with various levels of spectrum management. The communication challenges require investment in multiple technologies for leveraging communications across the radio frequencies and ultimately the optical spectrum. The impediments to unmanned systems communications are largely restricted to better use of the spectrum through investment in technologies that expand communication efficiencies. The problem today is largely a physics problem, which increases in complexity exponentially as one considers the air, ground, and maritime domain challenges. The testing of cognitive algorithms that can opportunistically leverage communications facilitating advanced mission oversight or multisystem collaboration remains in its infancy.

7.4 Way Ahead

Current DoD policies and guidance stress the need for new systems[30] to have a balance among improved interoperability; increased agility[31]; greater adaptability; improved spectral efficiency; compliance with U.S. national, host nation, and international spectrum policies[32]; and lower production costs. The ability to update and reconfigure parts of a communication system by software changes (e.g., software-defined radios) has been available for several years. In addition, these systems should conform to a standards-based architecture (e.g., service-orientated architecture) that supports multiple networks to enable rapid and transparent configuration changes without removing the radios from operation. Such multiple-input, multiple-output (MIMO), multicarrier, and multiwaveform capabilities, along with the software control of these functions, are needed within future subsystem developments. Ultimately, it is desired that these reconfiguration changes be done "automatically" so the systems adapt dynamically (Figure 11. Autonomy Roadmap.) in response to sensed changes in the operational environment[33] (> 2020).

The need to support operations in which there are intermittent wireless propagation links has become common place. This support has resulted in increased use of advanced error control coding, MIMO configurations, various path diversity techniques, integrated networking, and data diversity — all to provide improved end-to-end quality of service. Future effectiveness of unmanned communication systems is contingent on continued advancements in antennas,

[27] Both in CONUS and OCONUS.

[33] Also see Section 5 of this Roadmap.

2837 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

transmit/receive systems, underwater communications, spectrum considerations, signal processing, network systems, and optical communications. A description of those advancements is given in the following subsections.

> … Reinvigorate the industry's independent research and development and protect the defense industrial base.
>
> *–Under Secretary of Defense Memorandum for Acquisition Professionals, Better Buying Power, September 2010*

7.4.1 Antennas

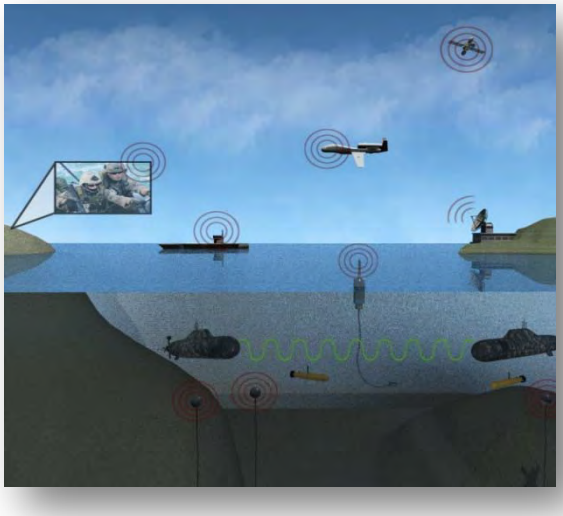
Communication with highly mobile systems requires high-gain, rugged, and lower cost multidirectional antennas. The larger UAS systems may also use highly focused beams to achieve connectivity with more distant systems.[34] Developments in phased array antennas and "smart" antennas (to include combining signals from multiple antennas) could offer an alternative to traditional dish antennas; however, they require tradeoffs among SWaP-C. DoD and industry will need to continue developing such techniques as multifocused and super-cooled antenna systems. The multi-focused systems would permit multiple users to receive information and not rely on point-to-point systems and subsequent relaying of data via other communication systems to local users.

Future antenna systems need to be able to send and receive signals over a broad range of frequencies. Phased arrays are a viable approach. For SWaP-C and low-profile considerations, phased array antennas need to be conformal (e.g., using metamaterial) that will be molded within the vehicle surfaces. The utilization of common apertures has called for the development of new interference mitigation methodologies that minimize co-site interference effects and improve the potential for achieving simultaneous transmit and receive operations within adjacent frequency bands.

7.4.2 Transmitter/Receiver Systems

Current transmitter solid-state power amplifiers (SSPAs) are typically made with gallium arsenide (GaAs) substrate. Gallium nitride (GaN) SSPAs, currently in development, provide significant advantages over GaAs SSPAs. They offer more than double the efficiency of GaAs amplifiers; they increase the amplifier operational bandwidth; and GaN SSPAs may provide for a wider range of frequency of operation. The high transmit efficiency of GaN systems will also reduce the cooling requirements. In order to achieve some of these benefits, the amplifier designs are being enhanced with adaptive operating point control that adjusts to the instantaneous power being demanded from the amplifier. This enhancement significantly reduces the average prime power required by the amplifier by allowing it to effectively turn itself off when not in use, yet adjusting to maintain proper conditions to ensure minimal distortion at higher instantaneous powers. The GaN technologies are currently available for selected frequency bands and will soon

[34] Global positioning system (GPS) has been used to aid in this connectivity.



2838 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

be available for fielding (2014). The amplifiers may also utilize signal-processing-based signal predistortion techniques to compensate for the basic nonlinearity of the amplifier's transfer characteristics.

Instantaneous bandwidth performance and analog-to-digital converter sampling speeds have continued to improve year after year.[35] In addition, improvements in integrated chip fabrication methods have allowed for significant miniaturization and reductions in part counts and for various transmit/receive and antenna functions and components to be integrated on a single chip (2013). Fiber optics has been used to speed up the data and signal transfers from and to the antenna and the signal processing hardware (2012).[36] Microminiature mechanical device developments should provide smaller size, more flexibility, and greater performance in receiver designs[37] (2015). Future developments are expected to provide improvements in reliability and fabrication yields, reduced thermal characteristics, reduced integration complexity, and lower production costs.

7.4.3 Underwater Communications

Ocean dynamics challenge underwater and surface communications and are unique to UUVs and USVs. These systems gain efficiency and effectiveness with real-time, two-way communications that do not undermine mission accomplishment. The Navy's *Undersea Dominance Roadmap* (under development) will identify current and future architectures to link UUVs, distributed netted systems, and tactical platforms. Future developments described in that roadmap will leverage existing technologies and potential new capabilities that will come through the Office of Naval Research S&T research and development efforts.

7.4.4 Spectrum Considerations

U.S. military operations are now occurring in many parts of the world where adequate spectrum is not available. There is a significant increase in the numbers of SDS being deployed by the United States, our partners, and our coalition forces to address current and expected future

[35] Lundberg, Kent H., *High-Speed Analog-to-Digital Converter Survey*, MIT Press, 2002.
[36] See the DARPA Optical RF Communications Adjunct and the Office of Naval Research's Enabling Capability programs. This application is more for ground-based systems than for airborne systems. This use also significantly minimizes the signal loss and allows more advantageous placement of selected components.
[37] C. T.-C. Nguyen, "Microelectromechanical devices for wireless communications (invited)," *Proceedings*, 1998 IEEE International Micro Electro Mechanical Systems Workshop, Heidelberg, Germany, Jan. 25-29, 1998, pp. 1-7.

2839 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

mission areas. In addition, these SDS collect more information, and missions often require greater bandwidths to send their information directly to warfighters. This latter consideration has been seen within OEF missions where new ISR UAS have included wide area surveillance sensors; alternative spectrum bands have been identified[38] to help address the wider bandwidths needed by those systems. Also, mission areas are becoming more spectrally "noisy" because of increasingly cluttered and hostile spectrum environments. As such, a continual demand for improved spectrum efficiency and effectiveness is being placed on all DoD SDS.[39] All unmanned systems must complete during their development process a spectrum supportability and risk assessment in accordance with DODI 4650.01 to identify and mitigate regulatory, technical, and operational spectrum supportability. Because national and international spectrum rules and policies can rapidly change,[40] developers should maintain a close liaison with appropriate DoD spectrum offices before finalizing communication system designs.

The use of LOS datalinks also supports missions where there is a denial of or impaired service to SATCOM systems. Under such conditions, the demand for LOS spectrum will be extended to support the need for improved spectrum use efficiency and effectiveness.

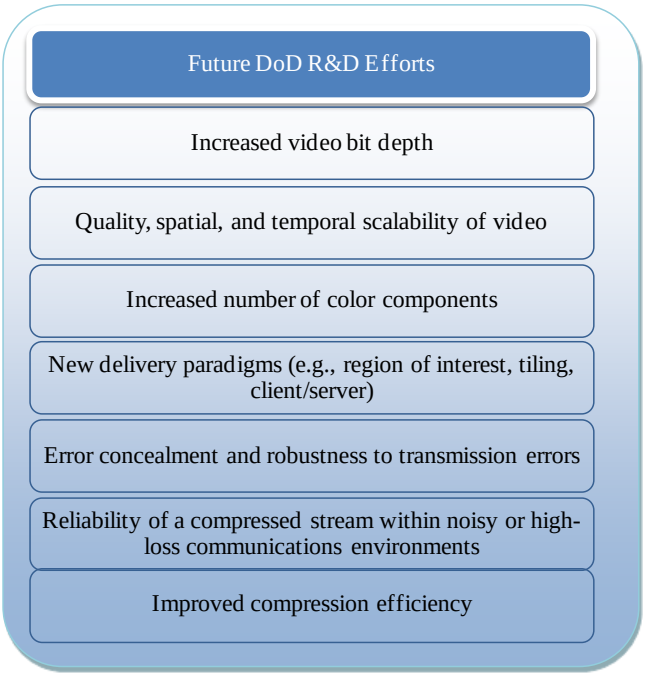
The Defense Advanced Research Projects Agency's (DARPA's) Next Generation (XG) project and its follow-on Wireless Network after Next (WNaN) program demonstrated the feasibility of dynamic spectrum access (DSA). DSA offers the ability to change frequency band use based on other adjacent SDS actual use and nonuse of certain bands. The Joint Tactical Radio System (JTRS) program is investigating the feasibility of integrating DSA technologies into its system. The U.S. Army is also considering having WNaN become part of an Army program of record. However, a recent USAF Scientific Advisory Board study said that DSA is far from being proven technology. Developmental challenges include susceptibility to countermeasures, costs of integrating with existing systems, developing standards (including regulatory aspects), and co-site interference (2015).

Alternative technology advances should aid in the spectral efficiency challenge to include internal and external EMI mitigation advances such as coherent signal cancellation, space-time adaptive processing, polarization diversity, and adaptive digital beam forming.

[38] OASD NII memo dated March 22, 2011 Subject: Department of Defense (DoD) Common Data Link (CDL) Usage in Operation Enduring Freedom (OEF) Theater

[39] All new and modified SDS programs now need to conduct a spectrum supportability and risk assessment prior to Milestone B (source: DODI 4650.01).

[40] Relatively near-term spectrum usage changes could come from the ITU and its 2011 Worldwide Radiocommunication Conference (WRC); UAS spectrum use is a conference agenda item. Changes in frequency band usage for UAS may also come from the FAA and the ICAO as part of the UAS operations in the NAS airspace and in other nation-states' airspace.



2840 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

7.4.5 Communications and Signal Processing

7.4.5.1 RF Waveforms

All ISR systems are to use the CDL waveform specification[41] whenever possible.[42] A mini-CDL system[43] is finishing development to allow CDL usage within smaller platforms than were possible in the past. Candidate future CDL waveform developments include adding a "dial-a-rate" capability for transmission speeds (with multiple bits-per-hertz and operating within the gigabit-per-second range) and a more efficient forward error correction (FEC) coding (both 2014). Also, several UAS program offices are pursuing such performance advances as more efficient CDL waveforms, operation in additional frequency bands, expanded communications security,[44] low probability of intercept (LPI) or low probability of detection (LPD), improved anti-jam, and greater link throughput. Corresponding improvements in surface and ground stations that receive the CDL signals have also been or are being made. There have also been significant efforts to improve commonality of these systems through the UAS Task Force and its I-IPT.[45]

Future CDL improvements will include, as feasible, the incorporation of advancements being offered by DARPA, industry, and academia. Four of the most appropriate DARPA programs that are being closely followed are the DARPA Interference Multiple Access and Disruption Tolerant Networking programs.

7.4.5.2 Preprocessing

Considering the anticipated large amounts of data projected to be collected by unmanned systems in an environment of limited bandwidth capability, one challenge is determining how much of that data needs to be sent back in near real time to a ground station. There is ongoing interest in addressing how best to select portions of images and to track those portions over time and send back "just" those selected images in near real time. These selection activities are currently being developed within classified TPED programs. As these activities progress, they should be applied in preprocessing efforts onboard

[41] These developments follow DODI 4630.09, DoD Wireless Communications Waveform Development and Management. The currently approved version is Standard CDL (STD-CDL) Rev H.
[42] The main reason for nonuse would be SWaP-C issues.
[43] This effort mostly focused on SWaP-C issues.
[44] Two cryptographic solutions (one classified and one unclassified) are used currently.
[45] See Section 4 of this Roadmap.

2841 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

unmanned systems. Improved preprocessing must be accompanied by sensor and processor miniaturization to reduce SWaP-C so as to maintain the persistent nature of UMS.

7.4.5.3 Compression

Compression techniques have tremendous potential to reduce bandwidth requirements, resulting in lower operating costs and increased operational flexibility. For example, FMV, synthetic aperture radar (SAR), inverted SAR (ISAR), and multispectral images can generate high bandwidth requirements (> 360 Mbit/s data rates). When compressed, the datalink bandwidth requirement could be in the range of only 1 to 30 Mbit/s.[46] Current compression techniques are described in the motion imagery systems matrix (MISM).[47] This matrix defines a recommended practice for the simple identification of broad categories of motion imagery systems. The intent of the MISM is to give user communities an easy-to-use, common shorthand reference language to describe the fundamental technical capabilities of DoD/Intelligence Community (IC)/National System for Geospatial Intelligence (NSG) motion imagery systems. The video quality needed for unmanned systems would nominally be MISM levels 4M/4H and 3M/3H. Currently the H.264 standard, which is firmly engrained in the commercial market,[48] offers twice the performance as Motion Picture Experts Group-2 standard (MPEG-2), and advanced encoding options will give even greater improvements[49] (albeit with potentially increased encoder latency).[50] The goal of the United Nations' ITU is for the H.265 standard to provide a chosen quality level at half the bit rate of H.264 (2018). For unmanned applications, future research and development should be undertaken by DoD and industry within areas depicted in the graphic on the right.

Beyond technical compression of all the collected data, there are logical advances that could reduce the amount of information that needs to be sent. This would include incorporation of logical bases for "just" replacing old information about a target's position with a more recent update, but not resending the unchanging background around the target.

> In addition to performance enhancements, compression techniques have tremendous potential to reduce bandwidth requirements and thereby reduce operating costs.

[46] Operational needs should determine the data rate that should be sent. Commanders in the field should be encouraged to require the lowest possible resolution and other parameters that meet their needs.
[47] See Motion Imagery Standards Profile (MISP) Recommended Practice 9720d, MISM, Standard Definition Motion Imagery.
[48] It is widely used within Blu-ray and digital video disk (DVD) systems.
[49] Over the past several decades, each generation of standardized video compression has provided a halving of the required bit rate for a given quality level relative to the prior generation.
[50] The latency introduced by some compression schemes can be so great that data links using such compressions cannot be utilized during such critical times as takeoffs, landings, and weapon launches.

2842 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

7.4.5.4 Encryption

Unmanned systems incorporation of data encryption includes National Security Agency (NSA) Type 1 (for protection of classified and unclassified information) or Federal Information Processing Standards (FIPS) Publication 140-2 certified solutions (for sensitive but unclassified information).[51] Several encryption solutions exist (e.g., Type 1 systems) for protection of unmanned systems communications (see DODI 4660). Numerous other policies and initiatives are under development within the NSA to significantly streamline the certification processes and reduce costs.[52] Future encryption solutions (2015) will inherently contain Suite B (public) encryption algorithms[53] to allow for secure classified information sharing with coalition and friendly forces. Additionally, an increasing number of encryption solutions will be based on such concepts as open standards for remote management; dynamic group keying (to support machine-to-machine information exchanges), common radio and system agnostic cryptographic interfaces (e.g., improving cryptographic component reuse and portability); software-based solutions for protection of classified data;[54] multifunctional single-chip data-in-transit and data-at-rest encryption; and single-chip all-encapsulated encryption modules (e.g., encrypt/decrypt/random key generation/key management).

7.4.5.5 Multiple Input, Multiple Output (MIMO) Systems

MIMO is a proven technology and is currently being used in commercial fourth generation (4G) wireless systems which have standards calling for a minimum of 100 Mbps for train and car speeds and 1 Gbps for stationary and walking speed. [55] MIMO combines information theory, FEC coding, signal processing, propagation theory, and consequently the mathematics behind MIMO and space-time coding is complicated. MIMO would utilize multiple paths (although not necessarily independent) with lower data rates on each path; apply space-time coding and capacity optimization to achieve a total high data rate mission; apply power saving to jammer margin; and evaluate performance in benign and stressed conditions.

With further improvements in E-discovery, interface design, and adaptive protocols, self-forming and self-healing mesh networks may enable unmanned systems to operate in multi-platform, multi-sensor type networks.

7.4.5.6 Protected Communications

In general, unmanned systems have been predominantly operated in benign environments. However, efforts are addressing improvements that are required to enable such systems to have assured and secure communications when operating in contested environments. These efforts leverage LPI, LPD, and Anti Jamming (AJ) activities that are underway in other communication systems developments. When moving UMS operations into contentious environments, a

2843 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

classified System Threat Assessment Report needs to be developed such that the appropriate LPI, LPD and AJ techniques are selected for incorporation into the system's design. LPD generally seeks to hide specific mission activities and involves techniques such as low power, spread spectrum, pulsed transmissions and/or directional antennas. Certain aspects of DSA could also benefit LPD. A key technique for LPI is the use of bit cover sequences within waveforms. AJ techniques include incorporating randomization at the protocol level and frequency hopping. Some aspects of DSA software implementation could offer some AJ protection.

7.4.6 Network Systems

Networking of multiple unmanned systems may be necessary to better ensure connectivity of the systems in non-LOS, urban, hostile, and/or noisy EMS environments to relay or transfer the collected information. One such concept under development is within the DARPA's LANdroids program,[56] which calls for the deployment of small, inexpensive, smart robotic radio network relay nodes that can leverage their mobility to coordinate and move autonomously. It seeks to demonstrate the capabilities of self-configuration, self-optimization, self-healing, tethering, and power management. Another concept would be the application of service-orientated architecture approaches to future network configurations.

7.4.7 Optical Communications

The application of lasers in unmanned systems communications could provide increased target detection capabilities, improved anti-jam performance, and decreased EMI within the communication subsystem. Optical communication systems are hampered by atmospheric absorption challenges, yet they offer far greater bandwidth (measured in gigabits-per-second) capabilities. LOS optical links have been successfully demonstrated at link ranges in excess of 50 km. Applications could apply to fixed locations and in air-to-air and ship-to-ship scenarios. Theoretical estimates indicate that air-to-ground links are feasible at rates up to 100 Mbit/s for link slant ranges up to 100 km, depending upon atmospheric conditions. Due to the extreme narrow beamwidth of such systems, maintaining pointing accuracy to and from a moving unmanned system will be a major challenge (> 2020).

7.5 Future Trends

Based on the force multiplier that unmanned systems have provided to our combat troops, it is expected that there will be a continued and increasing demand for supported capabilities communication systems. Those demands will include such capabilities as a single operator conducting more real-time analysis of multiple situations, while the unmanned system performs many of its assigned functions autonomously. Future communications equipment will need to be simple plug-and-play payloads that are easily, quickly, and cost-effectively modified, updated, and/or upgraded.

Future communications equipment will need to be simple plug-and-play payloads that are easily, quickly, and cost-effectively modified, updated, and/or upgraded.

7.6 Summary

There is tremendous worldwide competition for a finite amount of bandwidth. Concurrently, there is an increased demand for our unmanned systems to provide greater resolution, more persistent coverage, and continuous information flow. Technology supporting physical and software advances, and a fundamental shift in how we process and move vast quantities of data must be used to help overcome these conflicting requirements. Figure 15 provides a glimpse into the future capability and technologies we can expect throughout the course of this Roadmap.

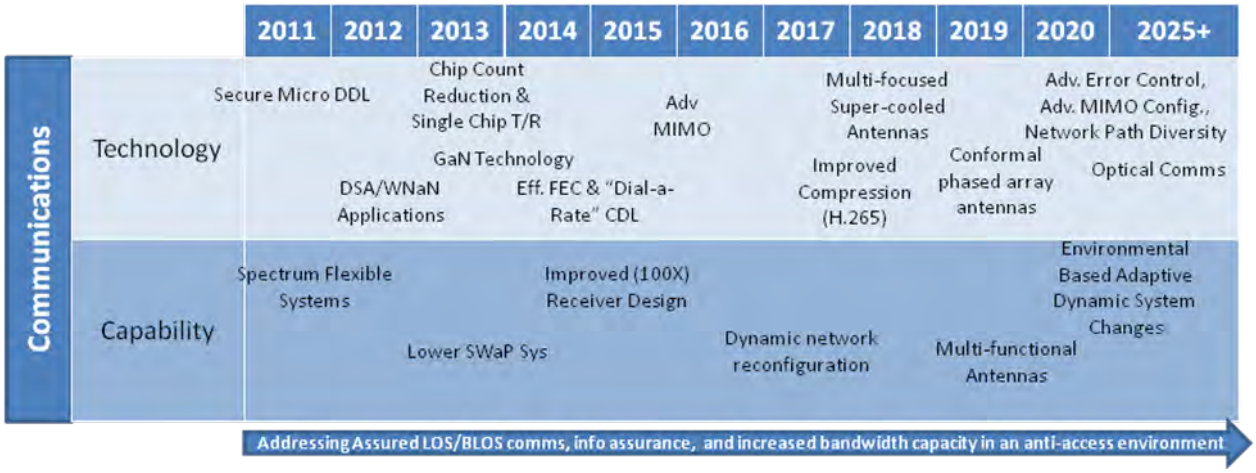

Figure 15. Communications Roadmap.

8 TRAINING

8.1 Functional Description

Training is a critical link in delivering warfighter capability. DoD can acquire and deliver the most technologically advanced piece of machinery, but if the operators, maintainers, and support personnel are not properly trained, there is no warfighting capability. The criticality of this fact is emphasized by the requirement for acquisition program managers to "work with the training community to develop options for individual, collective, and joint training" as part of the acquisition process.[57]

Training is a learning process that involves the acquisition of knowledge, sharpening of skills, concepts and rules, or changing of attitudes and behaviors to enhance performance. Once initial training is complete, proficiency is maintained through continuation and Joint training. Unmanned systems present a unique training challenge due to the following factors:

- Availability of training areas/NAS integration.
- Frequency spectrum management.
- The rapid proliferation of numbers and types of unmanned systems in response to wartime demand.
- Differing organizational perspectives on vehicle operator qualifications, sensor operator qualifications, and support personnel requirements across the growing number of systems in all classes of UAS, UGS, and UMS.
- The reality that most USAF day-to-day continuation training is accomplished under in-theater combat conditions due to the high demand for UAS assets in real-world contingencies. This trend provides limited opportunity for the USAF to integrate its unmanned systems in pre-deployment training as the Army and USMC routinely do.
- Lack of operator interoperability and universal design standards for unmanned systems control stations.
- Lack of formalized joint tactics across the Services.

8.2 Today's State

As unmanned systems have matured and acquisition programs of record have emerged in all Services, a concerted effort has been made to ensure, wherever practical and possible, that the Services share logistics costs and burdens to include training and training systems. To date, many success stories can serve as a template for moving toward the vision of maximum joint training standard(s) for unmanned systems:

- USMC and Army personnel operate a joint Shadow UAS qualification course at the Army's training facility in Fort Huachuca, Arizona. While the Navy does not operate

[57] DoD Instruction 5000.02 Operation of the Defense Acquisition System, December 8, 2008, p.61.

2846 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Shadows, Navy operators and maintainers were asked to help bridge a high-priority capabilities gap. This task was accomplished with no change in training hardware and software, simulation, or practical hands-on training. Navy personnel successfully deployed the Shadow system.

- The Chief of Staff of the Air Force and the Chief of Naval Operations signed a MoA to better utilize joint efficiencies in the Air Force Global Hawk and the Navy BAMS UAS programs. The goals of the working group are transparency between systems and a common work environment for both USAF and Navy operators.
- Army and Navy/USMC personnel share Raven B training and equipment, including maintenance requirements and GCSs.
- The JUAS COE[58] developed joint CONOPS, training qualification standards, and Tactics, Techniques, and Procedures for UAS.

Despite these success stories, given the DoD mandate to maximize training procedures and standardization for unmanned systems, the current state of unmanned systems training is still very much a work in progress.

The need for a comprehensive UAS training strategy was highlighted in UAS training workshops held in July and November 2009, hosted by the Office of the Deputy Assistant Secretary of Defense for Readiness, Directorate for Training Readiness and Strategy (ODASD(R)TR&S). The workshops were attended by all four Services, CCDRs, OSD, and Joint organizations involved with UAS issues. Additionally, a recent Government Accountability Office report recognized the lack of UAS training planning and called for the development of a DOD results-oriented strategy to resolve challenges that affect the ability to train personnel for UAS operations.[59]

> Provide soldiers and leaders the ability to excel in a challenging and increasingly complex future operating environment by developing tools and technologies that enable more efficient and effective training through live, virtual, constructive and mixed venues. Future training must enable the future force to impart more skills, faster, at lower cost and with greater retention than currently achievable. Soldiers and units must be able to be trained using non-traditional home station training techniques and technology and train prior to employment. Future training must enhance and account for individual proficiencies and learning rates (i.e. outcome based training). Future training and leader development must be completely adaptable and scalable to cover the full spectrum of operational challenges facing the Soldier.
>
> *– Capability Gap/Deficiencies, Robotic Systems Joint Project Office Unmanned Ground Systems Roadmap, July 2009*

[58] JCOE is being disbanded June 2011 and its tasks are being transferred to the Joint Staff and UAS Task Force.

2847 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

8.3 Problem Statement

As forces drawdown in theater and redeploy, the Services will require comprehensive continuation and Joint-forces training in the peacetime environment at beddown and selected Joint-training locations. Failure to prepare for this eventuality will result in a loss of combat gained experience.

8.4 Way Ahead

The ODASD(R)TRS is leading efforts to develop a comprehensive DoD UAS training strategy. The strategy will leverage the skills and expertise of each organization and build on foundational efforts already completed or underway within the Services. The study will investigate and assess the adequacy of existing and forecast joint, Service, and CCDR UAS plans and programs that identify and describe qualification, continuation, and joint training requirements and CONOPS. The strategy will identify and describe individual, unit, and large force training requirements of all groups of UAS. The result will be a UAS Training Roadmap that guides UAS training shortfall and mitigation analyses, provides UAS training recommendations, and proposes investment considerations for the UAS community. The UAS Training Roadmap will serve as a companion piece to this Unmanned Systems Roadmap to provide a total look at efforts related to delivering UAS capabilities to the warfighter.

Intuitively, some issues that will need to be addressed in the future include:

Policy: As attention shifts more towards day-to-day continuation training and UAS are further integrated into the NAS, unforeseen disconnects in the ability to train will need to be addressed in policy.

Education: UAS need to be habitually integrated into the kill chain in training scenarios. Commanders must be educated on the use of UAS as combat resources, and learn how to train with these relatively new assets. Tactical, Operational, and Strategic level UAS and ISR doctrine should be included in appropriate professional military education courses of instruction. Issues involving operator currency, flight minimums, and continuation training requirements must be learned and opportunities to train must be must be emphasized during home station training, combined exercises, and Joint Combined Training Center rotations.

Training Automation and Simulation: Rapidly expanding weapons systems capability requires associated expansion in training simulation. This expansion will need improved simulation fidelity and integration with live platforms for both effective/efficient use of resources. This will require improvements in training environments and classroom courseware.

Basing and Acquisition: As training requirements are defined, existing capabilities at proposed basing locations must be assessed against that which must be acquired to provide effective training.

9 PROPULSION AND POWER

9.1 Functional Description

The dramatic increase in the development and deployment of unmanned systems across the entire spectrum of air, ground, and maritime mission requirements has led to a concurrent increase in the demand for efficient, powerful, often portable, and logistically supportable solutions for unmanned system propulsion and power plant requirements.

For the purpose of this section, propulsion and power consist of the prime power to provide thrust and electrical power conversion, management, and distribution necessary for the operation of the electrically driven subsystems required to perform an unmanned vehicle's mission.

9.2 Today's State

A wide array of propulsion systems is used in unmanned systems, including combustion engines powered by heavy fuel or gasoline, jet engines, electric systems, fuel cells, solar power, and hybrid power systems. These propulsion systems can be divided into three groups according to vehicle size and mission: turbine engines, internal combustion, and electrical. The thresholds are not simple or clean cut, but are highly dependent on mission goals. Some of the parameters taken into consideration to determine the optimum propulsion system include size, weight, airflow, range, efficiency, and speed. Similarly, numerous power systems are in use, including batteries, engine-driven generators, solar power and hybrid systems.

The T&E of propulsion and power is critical as we consider a world of declining energy reserves and the strategic initiatives in alternative energy being made by the DoD.

9.3 Problem Statement

Endurance is perhaps one of the most compelling aspects of unmanned systems. While power and propulsion systems are much improved over comparable manned systems, the search continues for even more efficient systems to provide greater endurance, speed and range such as the X-51A Scram Jet shown in Figure 17 preparing for first flight.

Figure 17. X-51A Scram Jet.

2850 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

9.4 Way Ahead

9.4.1 Propulsion

> A primary long-term goal in aircraft propulsion is to reduce system specific fuel consumption by more than 30 percent over (current) gas turbine engines…. Technical challenges being pursued include efficiency, high-overall-pressure-ratio compression systems; variable-cycle engine technologies; advanced high-temperature materials and more effective turbine blade cooling; and techniques to more efficiently recuperate energy while satisfying thermal and power requirements.
>
> *– The National Plan for Aeronautics Research and Development and Related Infrastructure*

These challenges are currently being addressed for UAS applications under the highly efficient embedded turbine engine (HEETE) and efficient small-scale propulsion (ESSP) products, which are part of the Versatile Affordable Advanced Turbine Engines (VAATE) Program.

HEETE will demonstrate engine technologies that enable fuel-efficient, subsonic propulsion that supports future extreme endurance and range requirements with embedded engines incorporating complex inlets and exhausts. Covering the thrust class of 20,000 to 35,000 lbs, HEETE has two challenges: packing a high-bypass engine internally and delivering large amounts of electrical power regardless of throttle or flight condition. The HEETE design provides very small, high-powered cores to enable high bypass within the diameter constraints of an internally packaged engine. The propulsive efficiency is provided by highly efficient fans designed with the distortion tolerance needed to run behind complex inlets. The HEETE cores run at impressive pressure ratios, greater than 2.3 times the current state-of-the-art, and such ratios enable high tolerance of auxiliary power at high-altitude, long-endurance (HALE) altitudes. See Figure 18 HEETE cutaway view.

Figure 18. Highly Efficient Embedded Turbine Engine (HEETE).

2851 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ESSP will cover a full spectrum of technologies for propulsion systems for vehicles ranging from 100 to 2500 lbs. These products promise game-changing system capabilities. The S&T challenge to meet the ESSP goals is the simultaneous combination of high power density with high efficiency (low specific fuel consumption) in a design space not typically addressed by either gas turbine or piston engine systems (see Figure 19. Efficient Small-Scale Propulsion (ESSP).).

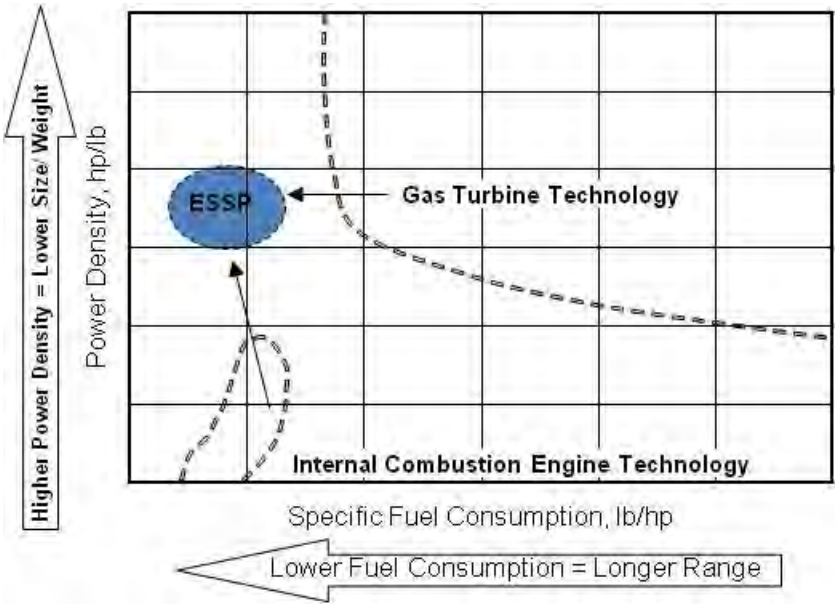

Figure 19. Efficient Small-Scale Propulsion (ESSP).

ESSP will conduct various demonstrations leading to reduced specific fuel consumption (SFC), increased power density, and a heavy fuel consumption capability. These demonstrations include a ducted fan, a nutating engine, a heavy fuel engine conversion, and a recuperator. ESSP is also designing and rig-testing high pressure ratio compressors and high temperature capable turbine concepts aimed at long-term capability.

The ducted fan is the most complex of the near-term demonstrations. The two main technologies to be demonstrated are the high-bypass geared ducted fan and the variable turbine nozzle. The test demonstrates the capability to run the high-bypass ducted fan with airflow from two different distributed core gas generators for maximum power during takeoff and maneuvering and then turning off one core gas generator, as a variable cycle feature, at cruise to cut the fuel consumption (conventional high-bypass turbofans would have to pull back the power setting to attain cruise condition, and this method would decrease engine speed, reduce the pressure ratio, and decrease component efficiencies resulting in increased SFC). The remaining core gas generator used to drive the ducted fan at cruise condition continues to operate at its design point for best cycle SFC. The variable turbine nozzle matches the airflow changes to maintain efficient turbine performance and drive the ducted fan.

The nutating disk engine leverages small business innovation research (SBIR) contracts for both the 4-inch and 8-inch disk engines. Both engines utilize the OSD SBIR-derived advanced microcomponents to enable engine performance potential. The major technical challenges are the

2852 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

development of micro-fuel injectors and radial engine seals and the understanding of the thermodynamics process. Both sizes of disk engine have undergone initial testing and show a significant increase in power density, to 1.38. The nutating disk is scalable to multiple UAV platforms by scaling the disk size.

The heavy fuel conversion engine, i.e., the Rotax used in the Predator, runs on aviation gasoline (AvGas, 100 octane). The Rotax concept demonstration is aimed at running the engine initially with lower octane fuels and ultimately with JP-8 heavy fuel. Engine testing has been completed successfully with 70 octane fuel. Although octane level is not specified for JP-8 fuel, fuel analysis to date has shown variations between a 20 to 50 octane level. Testing is on-going to demonstrate the operation of the Rotax engine on JP-8 fuel with targeted completion by the end of 2010. In parallel, there are SBIR efforts working to convert the Shadow UEL AR-741 engine to JP-8 fuel. Conversion efforts are aimed at maintaining engine performance levels while operating with JP-8 fuel.

The WTS126 turbo generator, developed by Williams International to drive the General Motors electric car, has a highly efficient recuperator, but is too heavy and large for installation into a flight vehicle. VAATE II studies indicated that a less efficient recuperator appeared to be the best balance among performance, size, and weight for a flight vehicle application. The WTS126 is an alternative heavy fuel propulsion system candidate for the Shadow. Testing and evaluation of the baseline WTS126 and the version with the less efficient flight weight recuperator are both underway.

For smaller platform applications, fuel cells offer an attractive alternative for internal combustion engines as field power generators, ground vehicle and aircraft auxiliary power units (APUs), and primary power units for small UAS. Fuel cells are devices that electrochemically combine fuel and air to produce high-quality electrical power. Because these systems do not generate power via combustion processes, they offer significantly lower SFC rates relative to advanced heavy fuel engines or diesel power generators (see Figure 20).

Solid oxide fuel cell (SOFC) systems represent a compelling power system option due to their high efficiencies, fuel flexibility, and low audible signature. Compared to other fuel cell approaches, the thermal environment and conductivity mechanism in SOFCs allow for a considerable improvement in fuel tolerance and provide a path forward for electrochemical logistic fuel operation.

2853 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

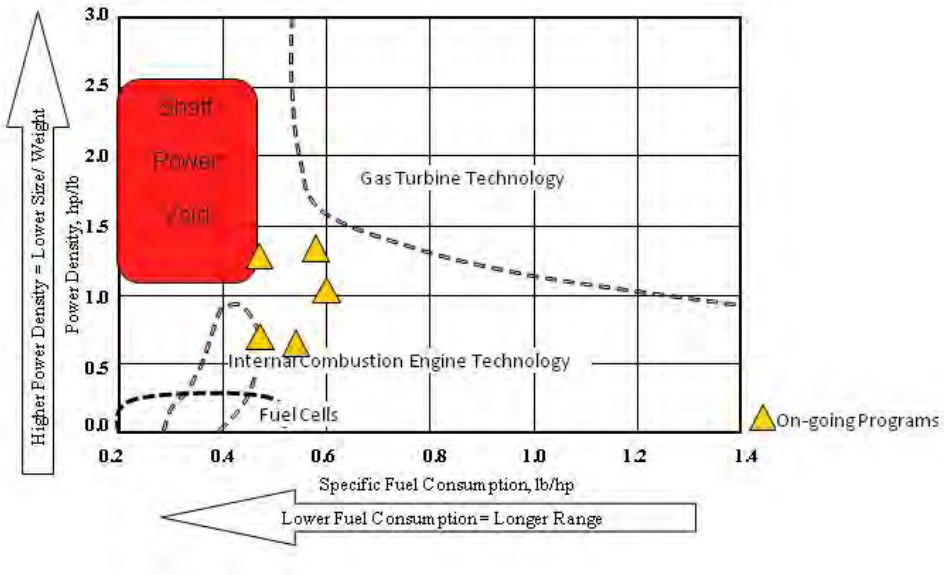

Figure 20. Fuel Cell Efficiency.

9.4.2 Power

Power sources are critical enablers for all of the desired unmanned systems capabilities. Improved power sources will have to be compact, lightweight, and reliable; provide enough power for the desired mission; and satisfy a full range of environmental and safety requirements. Design of power sources must be optimized for specific platforms and use profiles. Depending on the platform and mission requirements, applicable technologies may include energy harvesting (e.g., photovoltaic), electrical energy storage devices, fuel cells, and generators. It may be attractive to hybridize two or more of these technologies depending on the expected use profile. To implement these hybrid systems, the development of the proper control schemes must also be conducted. Recently, there has been a lot of effort invested to improve the power density of power generation systems with very good progress, but work is still needed to improve other power systems critical metrics. Some of these needed metrics and improvements are life, reliability, efficiency, optimized performance over varying engine speed, wide temperature range, production variability, control strategy, and parameters that capture the fact that unmanned subsystems typically do not have the redundancy of manned systems. Early scrutiny of the vehicle design will lead to improved power management. Form factor, materials, autonomy in sensor usage and route planning, and consideration of the undersea physical environment will minimize the energy demands and give back energy to extend the endurance or meet other mission goals.

Advances in mission equipment are providing much greater capabilities, but at a cost of greater demand for electric power, which results in greater power extraction from the engine. Power-sharing architectures allow for tailoring the source of power generation to minimize the cost in fuel burn. For example, if low-pressure (LP) power extraction is more economical than high-pressure (HP) power extraction, then the SSPCs can be turned on to power the bus that was previously powered by the HP-driven generator. Engine power extraction technologies related to power sharing between the HP spool and LP spool promise to provide significant benefit to

2854 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

bridging the gap between the platform power requirements and the engine power extraction limitations. Additionally, LP power extraction promises to provide improvements to SFC for overall air vehicle energy efficiency. Some of the key technologies needed to implement a power-sharing architecture are reliable power management control logics, high-power high-speed solid-state power controllers (SSPCs), a modulating generator control unit (GCU), and high-capacity electrical accumulator units (EAUs).

The HP GCU can be used to reduce the HP generator output and thus in a similar manner reduce the load on the HP spool to allow the LP generator to fulfill the power demand. The EAUs will be used to support radar peak-power demands and the power demands of short-duration, defensive-directed energy weapons.

9.4.3 Future Opportunity

Work is still needed to demonstrate the shaft power void. However, the large-engine approach of high overall pressure ratios (going to typical small-engine-corrected flow levels) is not available to small engines because of the physical size constraints of turbomachinary. Therefore, nontraditional configurations need to be emphasized to achieve the next level of capability.

Concerning battery chemistries and fuel cells, in the near term (up to 5 years), incremental power and energy performance improvements will continue to be made in the area of rechargeable lithium ion batteries. Lithium ion batteries will see broader military and commercial application, and significant cost reductions will be made as the manufacturing base matures. Near-term availability of small, JP-8 fuel-compatible engines is expected. There is mid-term (5 to 15 years) potential for significant incremental performance advances through the discovery and development of alternative lithium ion chemistries. Mid-term development of fuel cells with moderate power levels (100 W class) will begin to be introduced based on low-weight hydrocarbon fuels (e.g., propane). The technical feasibility of heavy hydrocarbon-fueled (e.g., JP-8) fuel cell systems will be proven at the kilowatt class. In the long term (beyond 15 years), there is the potential for revolutionary improvements through the discovery and development of completely new battery chemistries and designs. Figure 21 charts a course for power and propulsions capabilities and technologies.

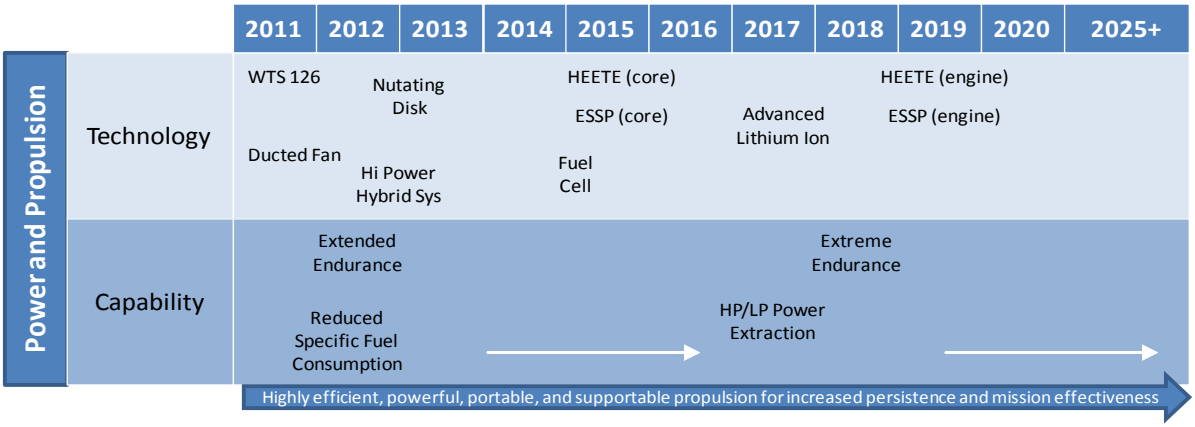

Figure 21. Propulsion and Power Roadmap.

2855 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

10 MANNED-UNMANNED (MUM) TEAMING

10.1 Functional Description

For this discussion, MUM teaming refers to the relationships established between manned and unmanned systems personnel prosecuting a common mission as an integrated team. More specifically, MUM teaming is the overarching term used to describe platform interoperability and shared asset control to achieve a common operational mission objective. This term also includes concepts of "loyal wingman" for air combat missions and segments of missions such as MUM air refueling. This capability is especially vital for missions such as target cueing and handoff between manned and unmanned systems, where the operators not only require direct voice communications between the participants, but also a high degree of geospatial fidelity to accurately depict each team member's location with regard to the object being monitored.

MUM teaming was first employed in the late 1960s when the USAF flew AQM-34 equipped with Maverick missiles from airborne C-130 aircraft. Over the intervening years, other experimental UAS were flown from manned aircraft and during the Predator ACTD from a submarine. In 2002, the USAF demonstrated the ability to fly the MQ-1 from a flying C-130 also equipped with a FMV camera to prove a rapid, small-footprint deployment capability, and the ability to cooperatively prosecute targets with onboard and off-board systems. The Army also conducted MUM demonstrations beginning with the Airborne Manned/Unmanned Systems Technology (AMUST) Demonstration in 2001 with a follow-on Hunter Standoff Killer Team (HSKT) ACTD in 2006. During that demonstration, an AH-64D executed level of interoperability (LOI) 4 control of a RQ-5B Hunter UAS during a live fire exercise where Apaches lased for their own Hellfire missiles with the Hunter payload.[60] At these demonstrations, the Army Aviation Applied Technology Directorate successfully integrated a Mobile Commander's Associate[61], including UAS control, Link 16, and other various data links, into an Army airborne C2 system. This integration enabled an airborne C2 system operator located in a UH-60 Black Hawk helicopter to control a Hunter UAS and its sensor, for the first time, as well as send and receive tactical information in flight between strike aircraft such as the FA-18, and reconnaissance aircraft such as JSTARS.[62] To date, each of the demonstrations merely changed the location of the control of the vehicle off the ground. This

2856 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

change was still significant because of the ability to more effectively conduct certain types of missions through collaboration of all assets.

10.2 Today's State

Practical applications of MUM teaming continue to evolve as confidence in unmanned vehicle reliability and functionality matures. Employment concepts are limited by data links, vehicle control interfaces, and level of autonomy. One recent example of practical application is when the USMC fielded a laser designation capability for Shadow as an enhancement/enabler of sensor-to-shooter operations for enemy/target of interest engagement in April 2010.

10.2.1 Unmanned Ground Vehicles (UGVs)

MUM teaming has steadily increased as technology has improved and users have found new and innovative methods to exploit this enhanced mission capability. Current missions include reconnaissance, surveillance, and target acquisition (RSTA); transport; countermining; explosive ordnance disposal; and the use of armed unmanned tactical wheeled vehicles for checkpoint security inspections. The integration of one-system remote video terminal (OSRVT) technology and distributed UGV control into ground combat vehicles is leading to the adaptation of TTPs because all parties now receive the same picture at the same time, regardless of their location.[63] With over 4,000 OSRVT or like systems fielded between the Army, USMC, and USAF to date, it is clear that MUM teaming is becoming ever more pervasive in ground operations. These developments have also been the catalyst for the creation of the common robotic controller, a joint project between the Army and USMC to develop a universal, wearable controller to operate a wide variety of unmanned systems, including UGVs, UA, and unattended ground sensors. This effort is currently aimed at smaller platforms, but could be transitioned to include limited control (i.e., payload only) for larger platforms as the technology matures.

[6363] Lt. Col. Adam Hinsdale, former Chief, UAS Division, Department of the Army Aviation Directorate, was quoted in October 2007: "Everyone, regardless of the platform, receives the same information at the same time, leading to true interoperability, the Army's key goal. The OSRVT is a vital component of manned/unmanned teaming, allowing all elements, air and ground, to view the same synchronized area of interest simultaneously for coordinated engagement, with either kinetic or nonkinetic effects." *UAS Video Terminal Connects Boots On The Ground To Eyes In The Sky*, by Kim Henry, Redstone Arsenal, AL, (AFNS), 9 October 2007.

2857 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

10.2.2 Unmanned Aircraft Systems (UAS)

MUM teaming has been successfully demonstrated in combat operations to provide CCDRs with enduring surveillance of hostile activities in real/near-real time to accurately geolocate potential targets, to laser-designate targets, and to provide battle damage assessment. UAS have proven successful in performing their missions largely because they are able to remain visually and aurally undetected by hostile forces. They are providing the CCDR with critical tactical data, which are used to plan and support combat operations. When used in support of ground operations, UAS have proven invaluable in providing near-real-time intelligence to commanders engaged in combat and have directly contributed to successful mission completion. Armed UAS have the ability to engage targets directly or cooperatively with other air and ground systems. Additionally, LOI 3 (control and monitoring of the UA payload in addition to direct receipt of UA data) has been demonstrated successfully in combat operations with attack helicopter crews. The attack helicopter crew is able to see on their cockpit display the sensor outputs that give them overhead views to the target and surrounding area. This capability greatly enhances the attack helicopter crew's ability to identify, classify, and verify target locations to reduce the risk of fratricide. In September of 2010, the Army conducted an integration exercise featuring Apache helicopter pilots controlling Shadow, Hunter and Raven UAs.

The success of the exercise resulted in the inclusion of the LOI 2 and 3 UA control requirement into the AH-64, which gives the manned aircraft sensor and flight-path control and monitoring of the UA (less launch and recovery). The Apache Block III initial fielding is scheduled for 2012 and will incorporate LOI 2, 3, and 4 UA control. The AH-64 BLK III will have the capability to receive real-time UA FMV and the associated metadata (LOI 2), control the UA electro-optical/infrared (EO/IR) payload (LOI 3), and dynamically task the UA flight path (LOI 4), all from the front seat of the Apache. The initial combat operations in Afghanistan and Iraq validated the urgent need to integrate UAS capabilities with manned aircraft, specifically the attack platforms. Commanders recognized that they could dramatically reduce sensor-to-shooter times and improve situational awareness of helicopter pilots, while drastically reducing collateral damage and the potential for fratricide. They crafted an Operational Needs Statement for attack helicopter MUM teaming capability that led to a rapid prototype system for the Apache called Video from Unmanned Aircraft Systems for Interoperability Teaming – Level 2 (VUIT-2). The VUIT-2 system allows the AH-64 crew to receive video feeds from UA utilizing C-Band transmission. The Army has renamed this effort MUMT-2 and expanded it to UH-60 Black Hawk and OH-58D Kiowa Warriors.

Current MUM teaming applications are limited due to the fact the control interface currently requires a dedicated crew member to fly the UAS while another crew member flies the manned aircraft. However, some automated MUM mission segments are being developed. For example, the Navy and USAF have developed and demonstrated technology for MUM air refueling and have simulated cooperative MUM air combat missions.

2858 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

10.2.3 Unmanned Maritime Systems (UMS)

MUM teaming is critical for the maritime environment. This is especially true for the undersea domain where physics prevent man from safely performing tasks to the same fidelity. There are many different aspects of MUM teaming for UMS that have been explored and implemented in various degrees: long-endurance undersea gliders send data ashore and receive human-initiated mission updates in near real-time; UUVs enable efficient port security, harbor defense, and mine clearance operations through change detection and autonomous investigation of mine-like objects; likewise, UUVs extend the footprint of manned hydrographic and bathymetric survey platforms to gather higher volumes of data while enabling people to focus on the tasks that require human oversight. Near-term enhancement, development and codification of Water Space Management/Prevention of Mutual Interference (WSM/PMI) doctrine and procedures will allow sophisticated collaboration between submarine or surface vessel operations and unmanned assets for mission accomplishment. Given the inherent challenges of the maritime environment, the future of MUM teaming will consist of multiple types of unmanned systems (UUV, USV, UAV, UGV) used collaboratively with manned platforms to collect, process, exploit, and disseminate data. An enduring and integrated net of undersea sensors partnered with USVs or UAVs for communication and controlled from a common command center will revolutionize how undersea missions are conducted by bringing transparency to an otherwise opaque battlespace. All maritime missions will benefit from reduced timelines and improved accuracy of information from which the combat commander can make engagement decisions.

10.3 Problem Statement

While strides have been made over the past decade to further enhance MUM teaming capabilities, several challenges persist that will continue to affect the amount of time it takes this technology to transition from the invention and adaptation phase to the acceptance phase. This timing will also directly affect the development of MUM teaming TTPs, which in turn will dictate the speed of MUM teaming from CONOPS into DoD doctrine.

Some of these challenges are technical. They range from near-term issues such as the limited ability to integrate and deconflict various radio frequencies across a secure communications network, to far-term issues such as the ability of one person to control multiple UASs and UGVs simultaneously while flying his or her primary aircraft. This ability requires a high degree of hardware and software interoperability, scalable autonomy, human system interfaces (HSIs), new collaborative control algorithms, and network mission tools. The platforms must do significant levels of onboard processing to not only reduce bandwidth required, but also collaborate with other unmanned vehicles without operator input. Other technical challenges result from the need to make tradeoffs between size, weight, and power limitations on the various platforms and the desire for increased performance and capability. One of the biggest potential challenges to MUM operations stems from the Services' desire to introduce swarms (large numbers

2859 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of micro-UAS operating semi-autonomously) into military operations with other manned and unmanned systems.

> "Everyone, regardless of the platform, receives the same information at the same time, leading to true interoperability; this is the Army's key goal.
>
> - *Lt. Col. Adam Hinsdale, Chief, UAS Division, Department of the Army Aviation Directorate*

Other MUM missions have different challenges including cargo, air refueling, interdiction in contested areas, electronic/network attack (EA), suppression of enemy air defenses (SEAD), and other traditional air combat missions. The ability to communicate from a highly maneuverable aircraft to a highly maneuverable future UAS will require significant advances in autonomy and HSI. This advancement can be compounded if LPI communication is needed for missions such as EA, SEAD, or control of long-dwell insect-size vehicles collecting information inside buildings.

10.4 Way Ahead (2011–2036)

Some key events will affect the future of MUM teaming over the next 25 years. As improvements in communications and sensor technologies evolve, new tactics will surely follow. For instance, it should be expected that there will be a shift away from the current reliance on video with operators incorporating other sensors (such as audio or tactile) to augment the tactical picture. Also, as commanders continue to integrate multiple manned and unmanned systems into their operations, they will soon be able to implement a "field of view" approach, similar to the "God's eye" perspective seen in many current video games. A commander will be able to view a target from multiple perspectives (i.e., UGV, UAS, or manned sensors), using multiple sensors, to obtain more robust and comprehensive situational awareness. As MUM advances, new HSI and autonomy will change the role of people in mission execution and dramatically increase their effectiveness.

The most significant advances in MUM operations will begin as Services migrate away from the current closed-loop scenario between sensor and shooter to networked systems. High endurance UAS already have mission teams geographically separated from the platform and from each other. Wide-area sensors are also changing the paradigm on STANAG 4586 LOIs and USIP development. Employing MUM segments as nodes on a larger network will change how missions are executed and will dramatically affect the combat effectiveness.

Investments in technologies such as automated air refueling, tactical data link control of maneuverable aircraft, and autonomy in the near term will enable "loyal wingman" operations. The effectiveness of air missions will not be achieved by a collection of assets, but collaboration between manned and unmanned systems within the context of a network. These nodes on the network will have scalable transparent control, not the brittle closed-loop control and inflexible autonomy algorithms used today.

2860 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

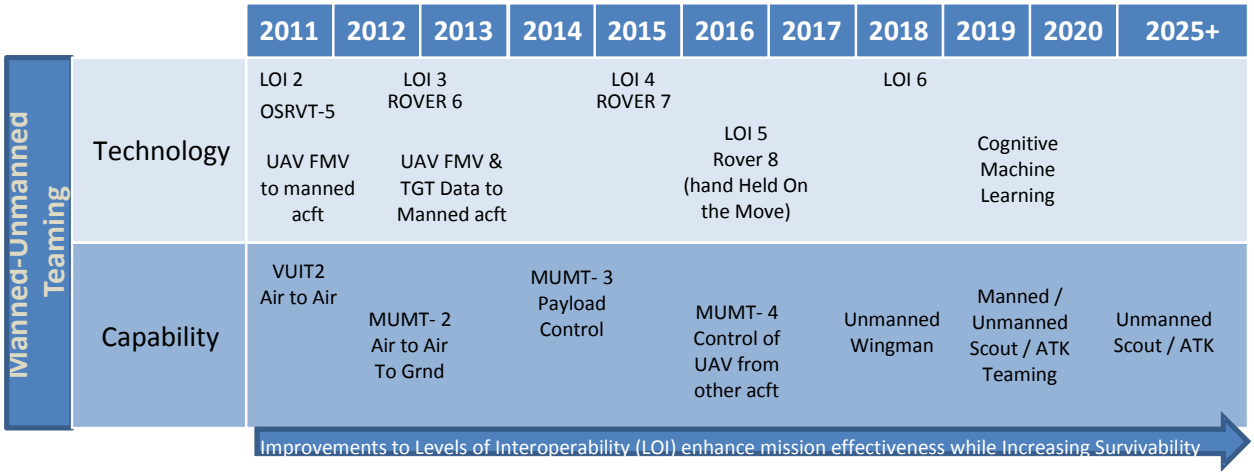

Figure 22. Manned Unmanned Teaming Roadmap.

The rapid growth in the OPTEMPO and demand for unmanned systems is a validation of their value to the CCDR. New concepts for the use of UAS, UGS, and UMS will result from experiences gained in combat. In the near future, it is likely that MUM teaming will be incorporated into an expanded set of operations.

2861 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

11 SUMMARY

DoD has made great strides in developing, producing, and fielding unmanned systems. These systems have been effectively integrated across air, ground, and maritime domains to support a wide range of Joint warfighting needs. The inherent advantages of unmanned systems, including persistence and reduced risk to human life, have been clearly demonstrated in combat operations in Iraq and Afghanistan.

DoD envisions the continued expansion of unmanned systems in the future force structure. This expansion will include fielding additional systems in capability areas already supported by unmanned technologies, but also expanding into new mission areas not currently covered. As DoD defines a path toward this vision, a common set of challenges is apparent that cuts across all military Services, budgets, and all three domains of air, ground, and maritime. DoD, working together with industry, academia, and other Government agencies, will continue to map an affordable path forward to address these common challenges. Success in addressing the common issues discussed in this document and following the technology roadmaps summarized in Figure 23 (see next page) is critical to achieving the full potential offered by unmanned systems technologies.

2867 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

APPENDIX C: GLOSSARY

Analysis and Production – The ability to integrate, evaluate, and interpret information from available sources and develop intelligence products that enable situational awareness.

Battlespace Awareness – The ability to understand dispositions and intentions as well as the characteristics and conditions of the operational environment that bear on national and military decision-making.

Building Partnerships – The ability to set the conditions for interaction with partner, competitor or adversary leaders, military forces, or relevant populations by developing and presenting information and conducting activities to affect their perceptions, will, behavior, and capabilities.

Collection – The ability to obtain required information to satisfy intelligence needs.

Command and Control – The ability to exercise authority and direction by a properly designated commander or decision maker over assigned and attached forces and resources in the accomplishment of the mission.

Communicate – The ability to develop and present information to domestic audiences to improve understanding; and, to develop and present information to foreign audiences to affect their perceptions, will, behavior and capabilities to further U.S. national security or shared global security interests.

Communicate Intent and Guidance – The ability to promulgate a concise expression of the operational purpose, assessment of acceptable operational risk, and guidance to achieve the desired end state.

Decide – The ability to select a course of action informed and influenced by the understanding of the environment or a given situation.

Deployment and Distribution – The ability to plan, coordinate, synchronize, and execute force movement and sustainment tasks in support of military operations. Deployment and distribution includes the ability to strategically and operationally move forces and sustainment to the point of need and operate the Joint Deployment and Distribution Enterprise. (JL(D) JIC pg 5 and pages 14-21)

Direct – The ability to employ resources to achieve an objective.

Engagement – The ability to use kinetic and non-kinetic means in all environments to generate the desired lethal and/or non-lethal effects from all domains and the information environment.

Force Application – The ability to integrate the use of maneuver and engagement in all environments to create the effects necessary to achieve mission objectives.

Health Readiness – The ability to enhance DoD and our Nation's security by providing health support for the full range of military operations and sustaining the health of all those entrusted to our care.

Information Transport – The ability to transport information and services via assured end-to-end connectivity across the NC environment.

2868 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Intelligence, Surveillance and Reconnaissance – The ability to conduct activities to meet the intelligence needs of national and military decision-makers.

Intelligence, Surveillance and Reconnaissance Dissemination – The ability to present information and intelligence products that enable understanding of the operational environment to military and national decision-makers.

Intelligence, Surveillance and Reconnaissance Planning and Direction – The ability to synchronize and integrate the activities of collection, processing, exploitation, analysis and dissemination resources to meet information requirements of national and military decision-makers.

Kinetic Means – The ability to create effects that rely on explosives or physical momentum (i.e., of, relating to, or produced by motion).

Logistics – The ability to project and sustain a logistically ready joint force through the deliberate sharing of national and multi-national resources to effectively support operations, extend operational reach and provide the joint force commander the freedom of action necessary to meet mission objectives.

Maneuver – The ability to move to a position of advantage in all environments in order to generate or enable the generation of effects in all domains and the information environment.

Maneuver to Engage (MTE) – The ability to move to a position of advantage in all environments in order to employ force.

Maneuver to Influence (MTInfl) – The ability to move to a position of advantage in all environments in order to affect the behavior, capabilities, will, or perceptions of partner, competitor, or adversary leaders, military forces, and relevant populations.

Maneuver to Insert (MTI) – The ability to place forces at a position of advantage in all environments.

Maneuver to Secure (MTS) – The ability to control or deny (destroy, remove, contaminate, or block with obstacles) significant areas, with or without force, in the operational area whose possession or control provides either side an operational advantage.

Mitigate – The ability to minimize the effects and manage the consequence of attacks (and designated emergencies on personnel and physical assets.

Monitor – The ability to adequately observe and assess events/effects of a decision.

Net-Centric – The ability to provide a framework for full human and technical connectivity and interoperability that allows all DoD users and mission partners to share the information they need, when they need it, in a form they can understand and act on with confidence, and protects information from those who should not have it.

Non-Kinetic Means – The ability to create effects that do not rely on explosives or physical momentum. (e.g., directed energy, computer viruses/hacking, chemical, and biological).

2869 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Prevent – The ability to neutralize an imminent attack or defeat attacks on personnel (combatant/non-combatant) and physical assets.

Processing / **Exploitation** – The ability to transform collected information into forms suitable for further analysis or action.

Protection – The ability to prevent/mitigate adverse effects of attacks on personnel (combatant/non-combatant) and physical assets of the United States, allies and friends.

Shape – The ability to conduct activities to affect the perceptions, will, behavior, and capabilities of partner, competitor, or adversary leaders, military forces, and relevant populations to further U.S. national security or shared global security interests.

Supply – The ability to identify and select supply sources, schedule deliveries, receive, verify, and transfer product and authorize supplier payments. It includes the ability to see and manage inventory levels, capital assets, business rules, supplier networks and agreements (to include import requirements) as well as assessment of supplier performance.

Understand – The ability to individually and collectively comprehend the implications of the character, nature, or subtleties of information about the environment and situation to aid decision-making.

ABSTRACT

UNMANNED SYSTEMS: OPERATIONAL CONSIDERATIONS FOR THE 21ST CENTURY JOINT TASK FORCE COMMANDER AND STAFF, by MAJ Ronny A. Vargas, 95 pages.

The Fiscal Year (FY) 2001 National Defense Authorization Act (NDAA) signed into law a mandate directing the Department of Defense (DoD) to develop and procure Unmanned Systems through FY 2030. These unmanned air, ground, and sea systems are being designed to support Full Spectrum Operations (FSO) in a hybrid-threat environment. The impact for the 2020 Joint Task Force (JTF) is that it will operate with unmanned systems that will revolutionize the way it conducts its operations. Furthermore, the 2020 JTF will be required to leverage cutting-edge information technologies that will ensure a secure and collaborative command and control network in a security environment that is increasingly competitive due to the proliferation of advanced unmanned systems. The challenge then is to posture the 2020 JTF to integrate these revolutionary unmanned systems. The essential tasks are to ensure operational reach and establish operational access throughout operations which are increasingly ready to be accomplished with revolutionary unmanned systems in lieu of manned systems.

ACKNOWLEDGMENTS

I wish to first and foremost, thank my father for his courage and sacrifice in providing us the best possible opportunity to succeed and accomplish life goals not available to him. I would like to recognize my mother's courage and strength to deal with and overcome her battle with breast cancer.

I wish to thank to the CARL library staff for their unwavering support in ensuring that the material pertinent to this research was made readily available. Thanks to my Joint Service colleagues who took the time to point me in the direction of their respective Services research, doctrine, and ongoing projects. Special thanks to the CGSC instructors who time the time to listen to my ideas and provide their pertinent input. Thanks to the MMAS faculty, Dr. Baumann, Dr. Lowe, Dr. Coates, and Ms. Krueger for their insights and support throughout this process.

CHAPTER 1

INTRODUCTION

> We must recognize that we are living in a machine age and in interest of national defense 'cut its cloth' accordingly . . . in the commercial world, the machine has largely replaced manpower; we to the fullest degree must use machines in place of manpower in order to occupy and hold without terrific losses.[1]
>
> — *Cavalry Journal*, January 1930

The Fiscal Year (FY) 2001 National Defense Authorization Act (NDAA) signed into law a mandate directing the Department of Defense (DoD) to develop and procure Unmanned Systems through FY 2030.[2] These unmanned air, ground, and sea systems are being designed to support Full Spectrum Operations (FSO) in a hybrid-threat environment. The impact for the 2020 Joint Task Force (JTF) is that it will operate with unmanned systems that will revolutionize the way it conducts its operations. Furthermore, the 2020 JTF will be required to leverage cutting-edge information technologies that will ensure a secure and collaborative command and control network in a security environment that is increasingly competitive due to the proliferation of advanced unmanned systems.[3] The challenge then is to posture the 2020 JTF to integrate these revolutionary unmanned systems. The essential tasks are to ensure operational

reach and establish operational access throughout operations which are increasingly ready to be accomplished with revolutionary unmanned systems in lieu of manned systems.

Background

The FY2001 NDAA, in conjunction with the FY2007 NDAA, provides DoD with guidance on unmanned systems. The key points that the documents emphasize are, (1) identifying a preference for unmanned systems in acquisitions of new systems, (2) addressing joint development and procurement of unmanned systems and components, and (3) transitioning Service unique unmanned systems to joint systems as appropriate.[4]

The 2006 Quadrennial Defense Review (QDR) further identified four national security challenges for the 21st century. These challenges will require future joint platforms with (1) greater reach (independent reach), (2) greater persistence (ability to loiter over the target area), (3) improved stealth (ability to survive in contested airspace), and (4) improved networking (ability to operate within a joint multidimensional network).[5] In order to address these challenges the Department of Defense (DoD) invests heavily within Research and Development (R&D) Directorates. The lead R&D directorate for the Department of Defense is the Defense Advanced Research Projects Agency (DARPA), which focuses on creating multi-disciplinary innovative technologies

[4]Department of Defense, *FY 2009-2034 Unmanned Systems Integrated Roadmap* (Washington, DC: Government Printing Office, 2009), 4.

[5]These four challenges are: defending the homeland in depth; fighting the long war against radical extremists and defeating terrorist networks; preventing state and non-state actors from acquiring or using weapons of mass destruction; and hedging against the rise of a power or powers capable of competing with the United States militarily, http://www.csbaonline.org/publications/2008/06/carrier-based-unmanned-combat-air-system/ (accessed 26 November 2011).

2886 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to support the operational commander. Other R&D stakeholders are the Office of Naval Research (ONR) that focuses on producing revolutionary capabilities for the U.S. Navy (USN) and the U.S. Marine Corps (USMC); the U.S. Air Force Research Laboratory (AFRL) is responsible for the Air Force's Science and Technology Program; the USMC War Fighting Laboratory, Office of Science and Technology (OS&T) serves as the Office of the Secretary Defense (OSD) office of record for the Joint Capabilities Technology Demonstration (JCTD) program and Joint Testing and Evaluation (JT&E).

The unmanned systems developed by these R&D directorates not only address the challenges highlighted in the 2006 QDR, they also focus on three critical additional areas: first, reducing risks to the Service members while operating across the operational domains; second, replacing prolonged and mundane workloads performed by Service members; and third, enabling unprecedented operational capabilities throughout the air, ground and sea operational domains. In other words, the future operational capabilities from these revolutionary unmanned systems will support full spectrum superiority, which consists of persistent intelligence, surveillance, and reconnaissance (ISR) requirements, full-dimensional security, precise enemy engagement from extended standoff ranges, and unmanned sustainment operations/support with minimal forces on the ground. Due to the revolutionary speed and capabilities becoming available to employ UMSs across the operational domains (air, ground, and sea), the capability of seizing, retaining, and exploiting the initiative will dramatically facilitate the 2020 JTF throughout its operations.

> The surest way to achieve decisive results is to seize, retain, and exploit the initiative. Seizing the initiative dictates the nature, scope, and tempo of an operation . . . commanders use initiative to impose their will on an enemy or

2887 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

adversary or to control a situation. Seizing, retaining, and exploiting the initiative are all essential to maintain the freedom of action necessary to achieve success and exploit vulnerabilities.[6]

Primary and Secondary Research Questions

The following research questions will assist in focusing the research to be conducted: The primary research question is will the 2020 JTF be postured to utilize mandated unmanned systems? The secondary research questions will be (1) what future training will be required for the JTF to employ UMSs? and (2) how will the incorporation of robust UMS capability impact the organization of a JTF in 2020?

Assumptions

There are three assumptions that are considered in developing the framework of this thesis. First, that DoD continues to regard the benefits from employing UMSs demonstrated in OIF/OEF for future operations. Second, that DoD continues to regard UMSs as a vital platform in providing persistent ISR and strike capabilities to the JTF in lieu of manned aerial systems. Finally, that the U.S. Congress, domestic industry, and Academia continue to support DoD's vision on UMS Research and Development (R&D).

Definition of Key Terms

The following definitions are based on *the Autonomy Levels for Unmanned Systems (ALFUS)* Framework developed by the National Institute of Standards and Technology (NIST).[7] The document was produced by the Federal Agencies Ad Hoc

[6]Department of the Army, Field Manual (FM) 3-0, *Operations* (Washington, DC: Government Printing Office, 2008), Appendix A, A-1.

[7]Federal Agencies Ad Hoc Autonomy Levels for Unmanned Systems Working Group Participants, Autonomy Levels for Unmanned Systems (ALFUS) Framework,

2888 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Autonomy Levels for Unmanned Systems Working Group. The working group consisted of unmanned systems professionals from government agencies and their supporting contractors on a voluntary basis. The intent is to develop a lexicon for unmanned systems (definitions not based on the ALFUS framework will be cited with the corresponding source).

Anti-access. Refers to those long –range capabilities and actions to prevent an opposing force from entering an operational area. Also known as A2 (Joint Operational Access Concept, version 1.0, 17 January 2012, Executive Summary, i).

Area-denial. Refers to those short-range actions and capabilities designed to limit freedom of action within the operational area. Also known as AD (Joint Operational Access Concept, version 1.0, 17 January 2012, Executive Summary, i).

Autonomous. Operation of an unmanned system (UMS) wherein the UMS receives its mission from the human and accomplishes that mission with or without further human-robot interaction (HRI). The level of HRI, along with other factors such as mission complexity, and environmental difficulty, determine the level of autonomy for the UMS.

Autonomous Collaboration. The ability of a UMS to collaborate with one or more manned vehicles or UMS without the need for an external controlling element.

Classifications. The "R" is the DoD designation for reconnaissance aircraft. The "M" is the DOD designation for multi-role, and "Q" means unmanned aircraft system. The number "1, 2, 3 . . ." refers to the aircraft series of remotely piloted aircraft systems.

Volume I: Terminology Version 1.1, edited by Hui-Min Huang, National Institute of Standards and Technology, September 2004, www.nist.gov/el/isd/ks/upload/ NISTSP_1011_ver_1-1.pdf. (accessed 20 September 2011).

2889 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Additionally, a change in designation from “RQ-1” to “MQ-1” signifies the addition of armament, i.e. the AGM-114 Hellfire missiles (Author interpretation).

Fully Autonomous. A mode of operation of an UMS wherein the UMS is expected to accomplish its mission, within a defined scope, without human intervention.

Human Assisted. The type of HRI that that refers to situations during which human interactions are needed at the level of detail of task plans, i.e., during the execution of a task.

Human Delegated. The type of HRI that refers to situations during which human interactions are mainly at the task level.

Human Robot Interaction/Interface (HRI). The activity by which human operators engage with UMSs to achieve the mission goals. The Operator is the role assumed by the person performing remote control or teleoperation. The Supervisor monitors one or more robots with respect to progress on the mission, can task the robot(s) at the mission level, monitors mission progress, provides mission level directions, coordinates missions, and can assign an operator to assist a robot if needed. A commander would be an example of a person who performs the supervisor-only role.

Human Supervised. The type of HRI that refers to situations during which humans play the monitoring role and human interactions are mainly at the mission level.

ISR. (Intelligence, Surveillance, and Reconnaissance) An activity that synchronizes and integrates the planning and operation of sensors, assets, and processing,

2890 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

exploitation, and dissemination systems in direct support of current and future operations. This is an integrated intelligence and operations function.[8]

Joint Capability Areas (JCAs). Collections of like DoD capabilities functionally grouped to support capability analysis, strategy development, investment decision making, capability portfolio management, and capabilities-based force development and operational planning (J7- Joint Concepts to Capabilities Division (JCCD) JCA 2010 Refinement approved 8 April 2011, http://www.dtic.mil/futurejointwarfare/jca.htm).

Methods of Control. The interface, either software or hardware, such as a joystick, waypoint selection via a map interface, natural language, hand signals, etc., that operators use to control a UMS.

Operational Access. The ability to project military forces into an operational area with sufficient freedom of action to accomplish the mission (Joint Operational Access Concept, version 1.0, 17 January 2012, Executive Summary, i).

Operational Reach. The distance and duration across which a unit can successfully employ military capabilities. The limit of a unit's operational reach is its culmination point (ADRP 3-0, 22 September 2011, 4-5).

Remote Control. A mode of operation of a UMS wherein the human operator, without benefit of video or other sensory feedback, directly controls the actuators of the UMS on a continuous basis, from off the vehicle and via a tethered or radio linked control device using visual line-of sight cues, in this mode, the UMS takes no initiative and relies on continuous or nearly continuous input from the user.

[8]Chairman, Joint Chiefs of Staff, Joint Publication (JP) 1-02, *Department of Defense Dictionary of Military and Associated Terms* (Washington, DC: Government Printing Office, as amended through 15 November 2011), 171.

2891 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Robot/Robotic. An electro-mechanical system that can react to sensory input and carry out predetermined missions. A robot is typically equipped with one or more tools or certain capabilities, including knowledge so that it can perform desired functions and/or react to different situations that it may encounter.

Semi-Autonomous. A mode of operation of a UMS wherein the human operator and/or the UMS plan(s) and conduct(s) a mission and require various levels of HRI.

Sensor. Equipment that detects, measures, and/or records physical phenomena, and indicates objects and activities by means of energy or particles emitted, reflected, or modified by the objects and activities.

Sensor Fusion. A process in which data, generated by multiple sensory sources, is correlated to create information and knowledge. Sensor information, when fused, may yield immediately actionable combat information and/or intelligence. The capabilities are of four essential types: *Detection*, *Classification*, *Recognition*, and *Identification*.

Sensory Processing. Computing processes that operate either on direct sensor signals or on low-level sensory signatures to detect, measure, and classify entities and events and derive useful information, at proper resolutions and at levels of abstractions, about the world. Sensory processes can be organized hierarchically with proper relative spatial and temporal resolutions and organized horizontally with assigned but coordinated focuses.

Teaming. A method of operation where a system uses the combined sensing, information exchange, decision-making, and acting capabilities of humans and robots function together to carry out missions within the planned scope. In the situations of manned–unmanned teaming, air-to-ground teaming means that the manned system is in

2892 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the air with UMS on the ground. Similarly, there could be air-to-air, ground-to-ground, and ground-to-air types of teaming.

Teleoperation. A mode of operation of a UMS wherein the human operator, using video feedback and/or other sensory feedback, either directly controls the actuators or assigns incremental goals, waypoints in mobility situations, on a continuous basis, from off the vehicle and via a tethered or radio linked control device . In this mode, the UMS may take limited initiative in reaching the assigned incremental goals.

Telepresence. The capability of a UMS to provide the human operator with some amount of sensory feedback similar to that which the operator would receive if he were in the vehicle.

Tether. A physical communications cable or medium that provides connectivity between an unmanned system and its controlling element that restricts the range of operation to the length of the physical medium.

Unmanned System (UMS). An electro-mechanical system, with no human operator aboard, that is able to exert its power to perform designed missions. May be mobile or stationary. Includes categories of unmanned ground vehicles (UGV), unmanned aerial vehicles (UAV), unmanned underwater vehicles (UUV), unmanned surface vehicles (USV), unattended munitions (UM), and unattended ground sensors (UGS). Missiles, rockets, and their sub munitions, and artillery are not considered unmanned systems.

Limitations

The thesis framework is the following; first, it will not be a detailed unmanned system capability brief; the intent is to focus on the impact of these various systems on

2893 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the ability of the 2020 JTF to conduct operations. Second, an analysis of a revolution of military affair (RMA) is outside the scope this paper. Finally, the topics and research will remain unclassified and will not relate information, capabilities, or missions that have been classified otherwise.

Significance

The continued development of unmanned systems will revolutionize the operational capabilities of the 2020 JTF. First, it will continue to impact the entire doctrine, organization, training, materiel, leadership and education, personnel and facilities (DOTMLPF) analysis process. Most important for this thesis are organization and training. Second, a full spectrum superiority concept as outlined in Joint Publication (JP) 3-03, *Joint Interdiction*, can be achieved through the employment of unmanned systems throughout the entire joint area of operation in lieu of manned systems (see figure 1).

> The cumulative effect of dominance in the air, land, maritime, and space domains and information environment (which includes cyberspace) permits the conduct of joint operations without effective opposition or prohibitive interference.[9]

The significance of continuous UMS development for all leaders was aptly reflected in a statement by the US Forces Command (FORSCOM) commander, General (GEN) David M. Rodriguez, that "in my first 20 years in the Army we probably got about

[9]Chairman, Joint Chiefs of Staff. Joint Publication (JP) 3-03, *Joint Interdiction* (Washington, DC: Government Printing Office, 14 October 2011), I-10.

2894 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

20 to 30 new systems . . . in the 15 months [in Afghanistan], when I was a division commander, I got 172 new ones."[10]

Third, with the accelerated development and proliferation of unmanned systems, our allies and foreign militaries are procuring or developing their own unmanned systems programs. This proliferation of UMSs will impact the risk for the 2020 JTF throughout its operations, thereby creating an emphasis on counter-UMS mitigation considerations.

CHAPTER 2

LITERATURE REVIEW

The purpose of this thesis is to answer the primary research question: Will the 2020 JTF be postured to utilize mandated unmanned systems? The following literature review will assist in this research by focusing on the major concepts of unmanned systems in order to establish a common understanding of their capabilities and employment considerations.

The breakdown for this chapter is as follows: (1) reviews the base documents and the NDAA's that establish the mandate for DoD unmanned systems acquisition and development; (2) identifies the Service's UMS roadmaps and major programs; (3) highlights Joint DoD publications that establish the doctrinal framework for establishing a JTF; (4) investigates academic publications that provide justification for the incorporation of UMS throughout military operations; and (5) provides an overview of UMS proliferation both adversary and friendly.

Why is DoD investing in Unmanned Systems?

The Fiscal Year (FY) 2001 National Defense Authorization Act (NDAA) mandated DOD to develop and procure unmanned Systems thru FY2030. It mandated two requirements that (1) by 2010, one-third of the aircraft in the operational deep strike force aircraft fleet are unmanned and that (2) by 2015, one-third of the operational ground combat vehicles are unmanned. It further instructed DoD to provide a description and assessment of the acquisition strategy for unmanned advanced capability combat aircraft and ground combat vehicles planned. This report will include a detailed estimate

2896 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of all research and development, procurement, operation, support, ownership, and other costs required to carry out such strategy through the year 2030.[11]

The impact to the 2020 Joint Task Force is that it will operate in a foreseeable hybrid-threat environment with unmanned systems that will revolutionize the way it executes its missions. The complexity of this hybrid-threat environment will require the Joint Force Commander (JFC) and his staffs to collect, analyze, and disseminate information thru an integrated battle command systems network integrated with unmanned systems.[12] The DoD *Unmanned Systems Integrated Roadmap: FY2011-2036* provides a centralized source for DOD's vision for unmanned systems.

> The DOD vision for unmanned systems is the seamless integration of diverse unmanned capabilities that provide flexible options for Joint War fighters while exploiting the inherent advantages of unmanned technologies, including persistence, size, speed, maneuverability, and reduced risk to human life. DoD envisions unmanned systems seamlessly operating with manned systems while gradually reducing the degree of human control and decision-making.[13]

Joint Capabilities Areas (JCA)

The Department of Defense (DoD) established JCAs as the preferred method to manage UMS capabilities. Each JCA represents a collection of related missions and tasks

[11]National Defense Authorization Act for Fiscal Year 2001, Public Law 106-398, Section 220, U.S. Statutes at Large 114 (2001).

Battle space Awareness (BA) is focused primarily on ISR which utilizes the Tasking, Production, Exploitation, and Dissemination (TPED) process to translate the sensor data into a common picture. Current platforms that support BA are the Predator, Reaper, and RQ-4 Global Hawk. The immediate requirement for BA ISR platforms is to operate with full autonomy extending their persistence capabilities from days to weeks across all of the domains.[15]

Force Application (FA) is focused on maneuver and engagement. Current UAV platforms that support force application are the Predator, Reaper, and MQ-1C Gray Eagle. The immediate end state for UGVs is to support and execute dismounted offensive

[14]Ibid., 16.

[15]Ibid.

2898 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

operations, armed reconnaissance and assault operations. In maritime operations, unmanned surface vehicles (USVs) and unmanned underwater vehicles (UUVs) will support mine countermeasures (MCM), anti-submarine warfare (ASW), maritime domain awareness (MDA) and maritime security (MS).[16]

Protection platforms will assist in force protection (FORCEPRO), to include assuming tasks that are determined to be "dirty, dull, and dangerous." The immediate end state is for fully autonomous platforms to assume responsibility for FOB security, obstacle construction/breach, sophisticated explosive ordnance disposal, and casualty extraction and evacuation.[17]

Logistics is suitable for the employment of UMSs to deploy, distribute, and resupply units.[18] In March 2010 the A160T Hummingbird unmanned helicopter successfully completed a cargo delivery demonstration under a U.S. Marine Corps War Fighting Laboratory contract. The demonstration proved the Hummingbird's ability to resupply frontline troops operating in restrictive terrain. The A160T Hummingbird exceeded all of the demonstration requirements, being able to deliver at least 2,500 pounds of cargo from one simulated FOB to another located 75 nautical miles away under the required six hours.[19] Furthermore, a detachment from Marine Unmanned Aerial Vehicle Squadron 1 from Twenty-Nine Palms, California, completed the first combat of a

2899 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

K-MAX helicopter to deliver 3,500 pounds of food and supplies from Camp Dwyer, Afghanistan, to Combat Outpost Payne in Helmand province.[20] This platform and capability are in accordance with the Army's Logistics Innovation Agency's desire to develop unmanned cargo aircraft within the next 7-10 years, with an emphasis placed on the autonomy in its development.[21]

U.S. Air Force

At the outset of the Global War on Terrorism (GWOT), the UAS became the weapon of choice. The U.S. Air Force's *Unmanned Aircraft Systems Flight Plan 2009-2047* envisions a networked family of UASs. These next generation UASs will operate autonomously and provide an exponentially improved degree of operational capabilities which will be managed by the designated Joint Force Air Component Commander (JFACC), a role traditionally carried out by the USAF. These systems will consist of a common airframe and will perform varied tasks traditionally executed by manned platforms, such as attacking enemy air defenses, operating as an airborne warning and control aircraft (AWACs), and long-range bombers. Ultimately, the end state will be to reduce the logistical footprint and requirements of fixed wing formations (see figure 2).

[20]James K. Sanborn, "UAV delivers cargo in first warzone run," *Marine Corps Times*, 31 December 2011, http://www.marinecorpstimes.com/news/2011/12/marine-uav-delivers-cargo-in-first-warzone-run-123111/ (accessed 1 January 2012).

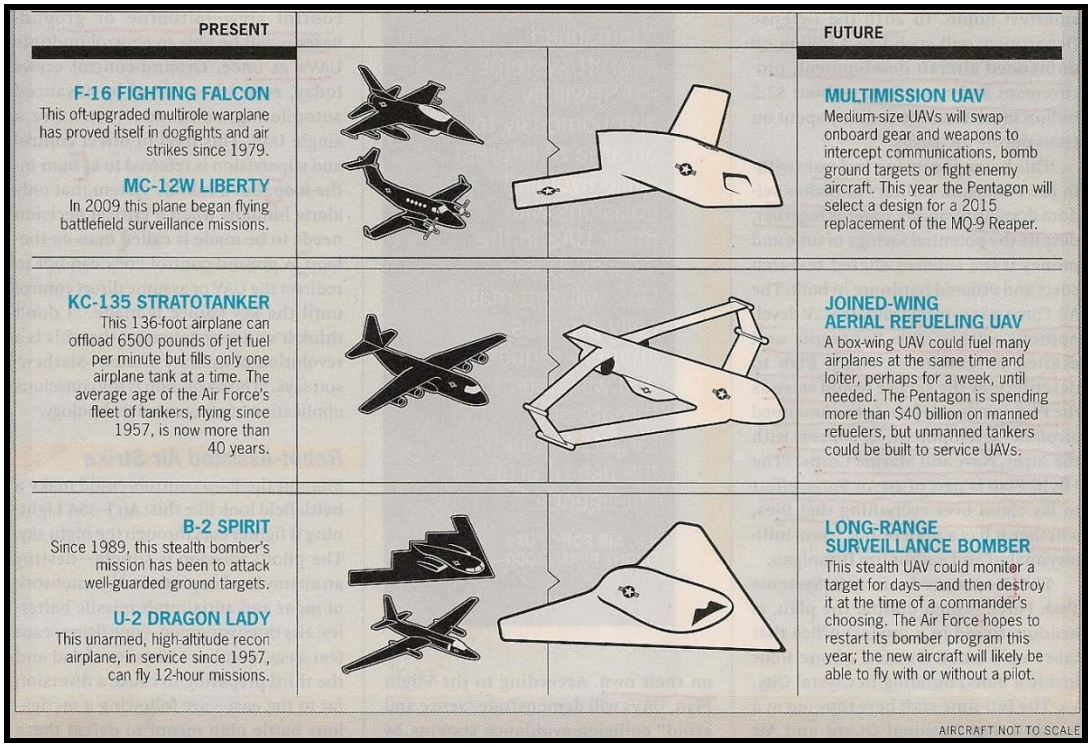

Figure 2. Non-DoD Manned and Unmanned UAV concept comparison

Source: Popular Mechanics, "Air Strike 2025, The Radical Plan to Reinvent the Air Force," March 2010, 59.

The U.S. Air Force's (USAF) vision for medium sized UASs (MQ-M) by 2020 is designed on a common platform and will contain an enhanced autonomous networked system. The MQ-M will evolve from the current medium-sized unmanned aircraft, Predator and Reaper, and it includes three phases of development, MQ-Ma, MQ-Mb, and MQ-Mc. In the first phase, the MQ-Ma's will be designed as a networked all weather platform supporting electronic warfare (EW), Close Air Support (CAS), Strike, and multi-intelligence (multi-INT) ISR missions. Additionally, the MQ-Ma allows for the flexibility to be controlled from mobile ground control stations. In the second phase, the MQ-Mb will merge capabilities from the MQ-9 Reaper and MQ-Ma in order to provide a

2901 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

wider spectrum of capabilities, which include Suppression of Enemy Air Defenses (SEAD) , Air Interdiction (AI), Special Operations (SOF) ISR, and the ability to conduct unmanned air refuel (see figure 3).[22]

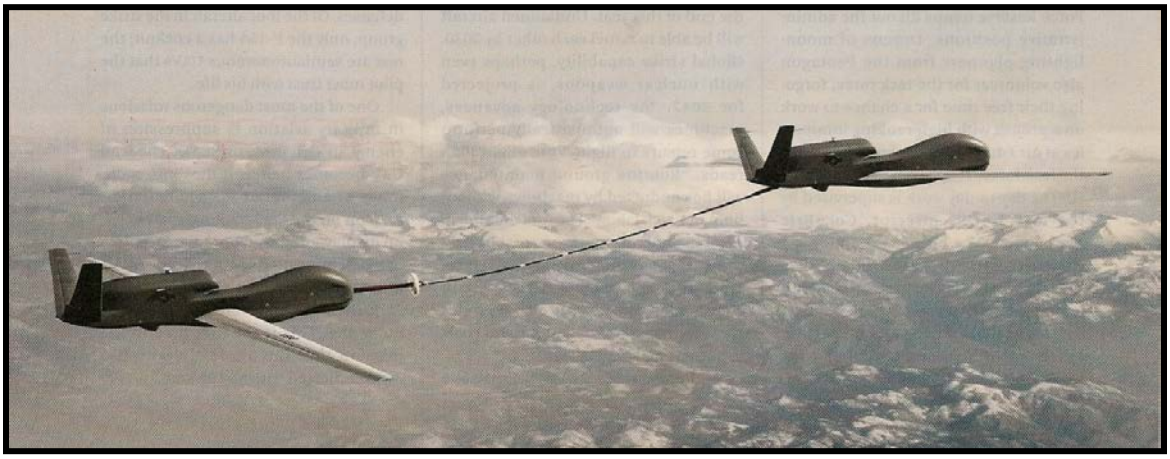

Figure 3. MQ-1 Predator in-flight refuel exercises circa 2007

Source: Popular Mechanics "Air Strike 2025, The Radical Plan to Reinvent the Air Force," March 2010, 59.

The advanced autonomous MQ-Mb will utilize SWARM technology which will allow multiple MQ-Mb aircraft to cooperatively operate at the control of a single pilot.[23]

[22]United States Air Force, *United States Air Force Unmanned Aircraft Systems Flight Plan: 2009-2047* (Washington, DC: Government Printing Office, 18 May 2009), 39.

[23]On 18 August 2011, Boeing announced the successful autonomous communications and operation of dissimilar unmanned aerial vehicles (UAV), which communicated using a Mobile Ad Hoc Network and swarm technology developed by Johns Hopkins University Applied Physics Laboratory. Swarm technology is similar to how insects communicate and perform tasks as an intelligent group. The UAVs worked together to search the test area through self-generating waypoints and terrain mapping, while simultaneously sending information to teams on the ground,

2902 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Finally, the MQ-Mc will possess the full spectrum of capabilities to assume manned system capabilities, such as Defensive Counter Air (DCA), Strategic Attack, Missile Defense and SEAD.

The U.S. Air Force vision for large-sized UASs (MQ-L) by 2020 will leverage autonomous capabilities and will also undergo three phases of development. In the first phase, the MQ-La will incorporate high resolution imaging Synthetic Aperture Radar (SAR) and Ground Moving Target Indicator (GMTI) capabilities, advanced signal intelligence (SIGINT) capabilities, and will operate in conjunction with the RQ-4 Global Hawk in multi-INT ISR missions. Furthermore, the USAF will design these platforms to replace manned battle management command and control (BMC2) platforms such as Joint Surveillance and Target Attack Radar System (JSTARs) and Airborne Warning and Control System (AWACS). Second phase, an all-weather MQ-Lb will be a multi-mission endurance aircraft providing ISR, EW, BMC2, and lift capabilities. In the third phase, the MQ-Lc will serve as the foundation for all missions requiring a large aircraft platform, such as air mobility, airlift, air refueling, EW, multi-INT ISR, Strategic Attack, Global Strike, CAS, and Air Interdiction operations.[24]

In summary, the USAF UAS Road Map supports the 2020 JTF essential tasks of providing operational reach and establishing operational access throughout its operations. The ability to accomplish these tasks with the projected unmanned systems in lieu of manned systems is in accordance with responsibilities outlined in JP 3-33, *Joint Task*

2904 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

U.S. Navy

The U.S. Navy (USN) is engaged in several major programs in support of UMS development and integration, such as the Littoral Combat Ship (LCS) as a command and control center for unmanned surface and undersea vehicles (USV/UUV), a vertical take-off unmanned air vehicle squadron (VTUAV), and the unmanned carrier-launched airborne surveillance and strike demonstration (UCLASS-D). The former Chief of Naval Operations (CNO) Admiral (Ret.) Gary Roughead stated that unmanned systems will be the future for the US Navy.[26] These unmanned systems are essential in supporting the Navy's global strategic presence mission, intelligence gathering, and extending the U.S. Navy's sea lines of communication (SLOCs). Furthermore, these unmanned systems will mitigate dangerous missions, such as conducting operations in the Arctic regions and mitigating anti-access/area-denial (A2/AD) threats.

In support of UMS integration, the U.S. Navy has designated the Littoral Combat Ship (LCS) to serve as a control center for both Unmanned Underwater Vehicles (UUV) and Unmanned Surface Vehicles (USV). The LCS is configured for various mission modules such as, anti-submarine warfare, mine countermeasures, anti-surface warfare, ISR, maritime intercept, and logistics. Several of these mission modules will be executed utilizing unmanned systems such as the Modular Unmanned Surface Craft Littoral, an ISR platform providing real time monitoring of vessels and personnel along waterways and shorelines.[27] An example of unmanned mine clearing operations, the U.S. Navy

2905 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

fielded the AN/WLD-1 RMS Remote Mine Hunting System, a three-foot-long robot that can detect mines underwater and carries a sensor payload that allows it to identify entities in the surrounding waters. In a mine-clearing operation in the port of Um Quasar, Iraq (2003), it cleared a square-mile area of mines within 16 hours; compared to the 21 days it would have taken USN divers to accomplish the same mission.[28]

In support of the vertical take-off unmanned air vehicle squadron (VTUAV) concept, the USN has conducted trial runs of the MQ-8 Fire Scout, an unmanned helicopter which is expected to dramatically cut the Navy's kill chain (the time it takes to identify, track and eventually engage an enemy target). The MQ-8 Fire Scout can neutralize or destroy fleets of small, fast moving boats used by drug smugglers and pirates. [29] The U.S. Navy recently conducted MH-60R Sea Hawk trials with the MQ-8 Fire Scout in order to extend the command and control (C2) and range of the MQ-8 Fire Scout.[30] This capability will allow for the coverage of thousands of miles of ocean determined to support wide area security operations (see figure 5).

2906 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

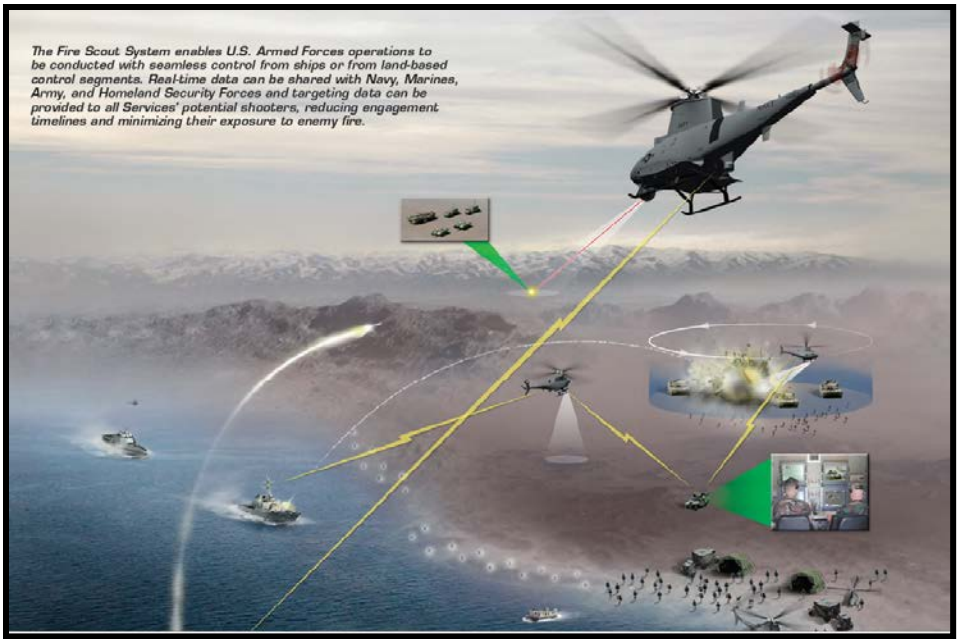

Figure 5. MQ-8 Fire Scout Unmanned Helicopter

Source: Northrop Grumman Corporation (2011).

The U.S. Navy's Unmanned Combat Air System Carrier Demonstration (UCAS-D) complies with the joint platforms envisioned in the 2006 QDR and has strategic deployment considerations.[31] The U.S. Navy is utilizing the UCAS-D to demonstrate the suitability of an UCAS Air Wing capable of operating in an unrefueled combat radius of 2,100 nautical miles (nm), exceeding current manned capabilities. Furthermore, with autonomous aerial refueling capabilities, loiter time for an UCAS/X-47B is 50 to 100

[31]"future joint air platforms with greater range (independent reach), greater persistence (ability to loiter over the target area), improved stealth (ability to survive in contested airspace), and improved networking (ability to operate as part of a joint multidimensional network) . . . the final Report of the 2006 QDR directed the Department of the Navy (DoN) to "develop an unmanned longer-range carrier-based aircraft capable of being air-refueled to provide greater standoff capability, to expand payload and launch options, and to increase naval reach and persistence . . . to field a low-observable unmanned combat air system (UCAS) that is capable of operating safely off of a carrier deck, and over longer combat ranges than contemporary manned carrier-based aircraft."

2907 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

hours (five to ten times longer than a manned aircraft). The UCAS/X-47B can conduct (without refueling) surveillance-strike combat air patrols at ranges out to 2,100 nm, with the capacity of a 4,500 pound weapon payload. In a strictly combat radius comparison, an F-35B Lighting II can operate within a radius of 485nm; F/A-18A-D Hornet within 500nm; AV-8B Harrier II within 300 nautical miles.[32] The U.S. Navy's UCAS-D will allow a dispersed UCAS aircraft carrier force to exert combat power over a significant area not achievable with manned aircraft and mitigate anti-area/area denial (A2/AD) threats (see figure 6).[33]

2908 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The U.S. Navy's emphasis on unmanned systems supports the 2020 JTF essential tasks of providing operational reach and establishing operational access throughout its operations. The ability to accomplish these tasks depends upon revolutionary unmanned systems in lieu of manned systems. Furthermore, with these unmanned capabilities, a U.S. Navy Numbered Fleet will garner further consideration to be designated as JTF HQ, as recently demonstrated in Operation Odyssey Dawn, which will be further discussed in this thesis.

U.S. Army

The *2009 Robotics Strategy White Paper* prepared by the Army Capabilities Integration (ARCIC) Center and Tank-Automotive Research and Development Engineering Center (TARDEC) focuses on the US Army's path forward in the procurement and employment of robots (also referred to as robotics).[34] The Army's use of robots, primarily to support EOD operations in Iraq and Afghanistan demonstrated the ability of unmanned systems to assist Soldiers in a wide range of mission support capabilities. The *2009 Robotics Strategy White Paper* highlights three critical opportunities for further development and procurement of unmanned systems. First, robotics reduces risks to Soldiers; second, robotics enabled platforms will reduce Soldier workloads; and third, robotics enables entirely new capabilities for extended range or stand-off reconnaissance operations. Additionally, the white paper identified and

[34]Department of the Army. *2009 Robotics Strategy White Paper*, prepared by the Army Capabilities Integration Center and Tank-Automotive Research and Development Engineering Center Robotics Initiative (Washington, DC, 19 March 2009).

2909 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

evaluated the feasibility of unmanned systems conducting and/or assisting with 32 tasks in the Universal Joint Task List (see Appendix A).

The *2009 Robotics Strategy White Paper* also recognizes and supports the four mission areas highlighted in the 2007 Office Secretary of Defense (OSD) Unmanned Systems Roadmap, (1) ISR - the number one operational commander priority, (2) target identification and designation - the ability to positively identify and precisely locate military targets in real-time, (3) conduct counter-mine warfare - Improvised Explosive Devices (IEDs) resulted in the number one cause of casualties in Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF), and (4) chemical, biological, radiological, nuclear, explosive reconnaissance - the ability to detect chemical, biological, radiological, nuclear, and explosive agents and to operate in these contaminated areas.

In addition to robotics and unmanned ground vehicle (UGV) development, the U.S. Army has engaged in manned-unmanned (MUM) trials, integrating UAVs with manned platforms, such as the AH-64D Longbow Block III attack helicopter (also known as the Apache). In a recent MUM proof of concept trial, Lockheed Martin outfitted the AH-64D Longbow Block III, with an Unmanned Aerial Systems Tactical Common Data Link Assembly (UTA).[35] The trial successfully demonstrated the Apache's ability to control the payload and flight of an MQ-1C Grey Eagle UAV in flight, validating the UTA's design in which "all goals of this phase of UTA testing were completed with 100 percent success."[36] The UTA control system will allow the Apache pilot to control the

[35]Lockheed Martin, LONGBOW UTA, http://www.f-16.biz/us/products/longbow_uta.html (accessed 12 March 2012).

In exploring the capabilities of utilizing unmanned helicopters, the 2010 Army Expeditionary Warrior Experiment (AEWE) validated that the MQ-8 Fire Scout's ability to provide the following capabilities: (1) support unmanned small unit resupply (2) provide the autonomous capability to transport and emplace unmanned ground vehicles/unattended ground sensors into the battlefield, (3) provide dedicated network communications relay, (4) ability to land/takeoff from unimproved surfaces, and (5)

---

us/news/press-releases/2011/november/LONGBOWLLCsDataLinkContro.html (accessed 12 March 2012).

2911 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

enhance situational awareness through persistent stare capabilities.[37] The AEWE is managed by the Maneuver Battle Lab at Fort Benning, in coordination with TRADOC Army Capabilities Integration Center (ARCIC) allowing for network-enabled small units to experiment in a live field environment with emerging technologies and concepts of operation.

The U.S. Army's emphasis on UMSs (UAVs, robots, and UGVs) will support the four mission areas previously outlined in the 2007 Office Secretary of Defense (OSD) Unmanned Systems Roadmap. The U.S. Army leveraging these UMS capabilities in lieu of manned systems will support the 2020 JTF essential tasks of providing operational reach and establishing operational access throughout its operations. Furthermore, UMSs fully support Army Operating Concept (AOC) constructs; combined arms maneuver (CAM) and wide-area security (WAS).

> Army forces conduct combined arms maneuver to gain physical, temporal, and psychological advantages over enemy organizations . . . Army forces integrate the combat power resident in the Army's six war fighting functions . . . to defeat enemies and seize, retain, and exploit the initiative.
>
> Army forces conduct wide area security to consolidate gains, stabilize environments, and ensure freedom of movement and action. Wide area security operations protect forces, populations, infrastructures, and activities.
>
> Army forces capable of combined arms maneuver and wide area security operations are an essential component of the joint force's ability to achieve or facilitate the achievement of strategic and policy goals.[38]

2912 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

U.S. Marine Corps

The *Marine Corps Vision and Strategy 2025* serves as the strategic planning document encompassing its legislated role, functions, and composition in order to conduct operations against hybrid threats in complex environments.[39] The supporting operating concepts outlined in this document establish its role as an expeditionary fighting force capable of operating in diverse operating environments. Furthermore, the Marine Corps will be able to lead joint operations and accomplish its missions with Marine Air-Ground Task Force (MAGTF) incorporating manned and unmanned platforms to support combined maneuvers.[40]

The DOTMLPF impact for the Marine Corps is on its: (1) Operating Force Structure; which recognizes the application of unmanned systems across the MAGTF, (2) on the Command Element (CE), which will need to provide persistent ISR in a complex operational environment, and (3) on the Ground Combat Element (GCE), which is tasked to enhance the maneuver capabilities of Marine ground forces within in a complex urban environment.[41]

The *USMC Vision and Strategy 2025* further requires: (1) continuous, all weather, precision fires, (2) the ability to rapidly and precisely engage asymmetric targets of

[39]Department of the Navy and United States Marine Corps, *USMC Vision and Strategy 2025* (Washington, DC: Government Printing Press, 2).

[41]Ibid., 20.

2913 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

opportunity, and (3) that the Aviation Combat Element (ACE) integrate UASs in order to expand the force-multiplying capabilities inherent in unmanned systems.[42]

The *Marine Corps Unmanned Aircraft System (UAS) Plan* recognizes the capabilities of UASs in lieu of manned aircraft throughout the MAGTF. The key enhancements are ISR, C2, Strike, EW, and combat logistics. The initial organizational change to the MAGTF is the establishment of the Marine Unmanned Aerial Vehicle Squadrons (VMU). Additionally, the Marine Corps will integrate various UAS platforms, such as: (1) small UAS (SUAS), such as the RQ-11 Raven, (2) small tactical UAS (STUAS), such as the Scan Eagle system, (3) Marine Corps Tactical UAS (MCTUAS), currently supported by the RQ-7B Shadow, and (4) future Group-4 MCTUAS, capable of Strike, ISR, and EW capabilities.[43] The FY16 end state is that the MAGTF will employ UASs in order to enhance its operational capabilities. Additionally, it will integrate UAS cargo platforms currently being utilized in Afghanistan, to support and execute unmanned logistical support requirements.

North Atlantic Treaty Organization (NATO)

> The globalization and the boom of information, computing, networking, satellite and precision technologies all have tremendous implications for the defense and security sector. The extensive use of modern technologies in the offensive campaigns in Kosovo, Afghanistan and Iraq enabled the military to

[42]Ibid., 21.

2914 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> achieve an unprecedented operational tempo and precision, and to win wars in the course of several weeks, instead of years.[44]

The NATO Defense Security Committee published a report authored by Pierre Claude Nolin (Canada), *Transforming the Future of Warfare: Network-Enabled Capabilities and Unmanned Systems*, focusing on network-enabled capabilities (NEC) and unmanned systems to assume missions in lieu of personnel or manned platforms in future conflict scenarios.[45]

> An information superiority-enabled concept of operations that generates increased combat power by networking sensors, decision-makers, and shooters to achieve shared awareness, increased speed of command, higher tempo of operations, greater lethality, increased survivability, and a degree of self-synchronization. In essence, [network-centric warfare] translates information superiority into combat power.[46]

The report asserts that NEC and unmanned systems are different technological development programs; however, "emerging drone technology is a physical extension of NEC and those NEC C4ISTAR systems will increasingly depend on Unmanned Aerial Vehicles (UAVs) as a tool to collect intelligence and reconnaissance data and even to

---

[44]NATO Parliamentary Assembly, Pierre Claude Nolin (Canada), General Rapporteur, 175 STC 07 E bis -*Transforming the Future of Warfare: Network-Enabled Capabilities and Unmanned Systems*. 2007 Annual Session, I-1.

[45]The Defense and Security Committee (DSC) examine ongoing operations, partnerships and programs to find how NATO can continually improve its effectiveness as an ally. The DSC focus: (1) military effectiveness, (2) interoperability, (3) defense transformation, (4) defense budgets, (5) organization of NATO military structure, (5) operational relations with other international organizations, particularly the European Union, and (6) progress of candidate and partner countries in meeting standards for integration into NATO operations and partnerships, i.e. STANAG 4856.

[46]NATO Parliamentary Assembly, Pierre Claude Nolin (Canada), General Rapporteur, 175 STC 07 E bis -*Transforming the Future of Warfare: Network-Enabled Capabilities and Unmanned Systems*. 2007 Annual Session, II-A-4.

2915 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

attack targets."[47] The inherent benefits of NEC enabled unmanned systems are the reduction of Soldiers and increased survivability. Additionally, the report recognizes the inherent benefits outlined in DoD roadmaps, such as: (1) reduction of personnel/logistical footprints within the area of operation, (2) assumption of the 3D (dull-dirty-dangerous) missions, (3) the use of ground or underwater drones in demining operations. It further proposes a price incentive comparison. A F-16 fighter aircraft costs $30 million; a MQ-9 Reaper with a similar payload capacity costs approximately $7 million. Moreover, a UCAV could be a cheaper alternative to manned fighter programs. One F-35 Joint Strike Fighter costs $100 million; an F-22 Raptor $200 million, while the estimated costs of X-45 UCAV is $40 million.[48] Additionally, UAS upgrades are flexible and can be tailored to meet emerging threats. In contrast, manned systems place "very strict limitations on the size, shape, speed, altitude and many other technical characteristics of an aircraft. Without these limitations, engineers can create machines that would change our understanding of what an aircraft can do and it could look like."[49] This NATO report further highlights two points: (1) the extent of UMS proliferation, which extends to 32 countries, developing more than 250 different UAV models, (2) UMS customers encompass, Europe, Middle East, North Africa and Asia, which are expected to capture nearly 40 percent of the global market.[50]

2916 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

DoD Publications

The purpose of reviewing DoD Joint publications is to analyze the doctrinal guidance on establishing a JTF and determine if the 2020 JTF will be postured to integrate and execute operations utilizing unmanned systems.

JP-1, *Doctrine for the Armed Forces of the United States* outlines the fundamental principles that guide the employment of US military forces in a Joint environment. It states that: (1) the strategic security environment is extremely fluid and that the Joint Force must be prepared to address emerging peer competitors and hybrid threats, (2) it will operate under the concept of Unified Action (UA), which refers to the synchronization, coordination, and/or integration of the activities of governmental and non-governmental entities to achieve unity of effort. Furthermore, UA demands maximum interoperability between all forces, units, and systems in order to operate together effectively across the spectrum of operations.[51]

JP 3-0, *Joint Operations*, provides the JTF guidance on planning, preparing, executing, and assessing joint military operations. It outlines six basic Joint functions which are common to most joint operations: (1) command and control, (2) intelligence, (3) fires, (4) movement and maneuver, (5) protection, and (6) sustainment. Furthermore, it addresses (a) organizing for joint operations, (b) organizing the joint force, and (c)

[51]Chairman, Joint Chiefs of Staff, Joint Publication (JP) 1, *Doctrine for the Armed Forces of the United States* (Washington, DC: Government Printing Office, March 2007, Incorporating Change 1, March 2009).

2917 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

conducting joint operations across the range of military operations, which includes the phasing of a joint operation.[52]

JP 3-33, *Joint Task Force Headquarters* (JTF HQ), outlines the formation and employment of a JTF HQ to command and control joint operations. It also outlines the JTF HQ organization and staffing and duties and responsibilities of the directorates, for the purpose of this thesis, the author will primarily focus on the J2 (Intelligence), J3 (Operations), and J4 (Logistics) and further describes the JTF functional commands; Joint Forces Air Component Commander (JFACC), Joint Forces Land Component Commander (JFLCC), Joint Forces Maritime Commander (JFMCC), and the Joint Forces Special Operations Commander (JFSOC).[53]

JP 5-0, *Joint Operation Planning*, forms the core of joint doctrine for joint operation planning throughout the range of military operations. It outlines: (1) the role of joint operation planning, (2) strategic direction and joint operation planning, (3) operational art and operational design, and (4) the joint operation planning process (JOPP).[54]

Additional Joint Publications relevant to JTF operations and to the discussion of UMS integration are: (1) JP 3-30, *Command & Control for Joint Air Operations*, (2) JP 3-31, *Command & Control for Joint Land Operations*, and (3) JP 3-32, *Command &*

2918 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Control for Joint Maritime Operations. Together, these set forth the doctrine for joint operations to their respective functional components; to include interagency and multinational operations. For example, JP 3-30 outlines the responsibilities for the JFACC such as command and control of joint air operations across the range of military operations. The UMS operational considerations for the JFACC where highlighted in the Joint Capability Area (JCA) discussion and further refined in the USAF *Unmanned Aircraft Systems Flight Plan 2009-2040*, which envisions a networked family of UASs. These next generation UASs will operate autonomously and provide an exponential degree of operational capabilities which will be managed by the designated Joint Force Air Component Commander (JFACC).

The discussion regarding the perceived future hybrid threat operating environment, from both DoD and academic institutions, has been clearly defined and adopted. *Training Circular 7-100, Hybrid Threat*, describes the hybrid threat and outlines the manner in which this future threat may operationally organize against US forces and allows for further discussion in the integration of UMSs to mitigate threats in this operating environment in lieu of manned platforms and/or personnel.

> Hybrid threats (HT) are innovative, adaptive, globally connected, networked, and can possess a wide range of technologies, including the possibility of weapons of mass destruction (see figure 8). Hybrid Threat (HT) strategy is multi-dimensional conducted in four strategic-level courses of action, (1) strategic operations aim is to preclude the JTF from intervening in the HT area of operation/influence,(2) regional operations-actions against regional adversaries and internal threats,(3) transition operations- HT continues to pursue its regional goals while dealing with the development of outside intervention with the potential for overmatching the HT's capabilities, and(4) adaptive operations-

2919 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

actions to preserve the HT's power and apply it in adaptive ways against overmatching opponents.[55]

The preparing agency is the Contemporary Operational Environment and Threat Integration Directorate (CTID), TRADOC G-2 Intelligence Support Activity (TRISA) –Threats).

2920 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The foreseeable WMD/CBRNE planning considerations for the 2020 JTF are: (1) proliferation of nuclear weapons; (2) neighboring nuclear armed states in conflict, such as Pakistan/India or North Korea/Japan; (3) conducting operations in a CBRNE contaminated environment, such as in the event of a nuclear reactor meltdown. The WMD/CBRNE scenario will require remote engagement with platforms possessing increased standoff capabilities, a dispersion of forces, and persistent ISR and Strike capabilities. In this scenario, the U.S. Naval forces will be forced to operate from dispersed platforms; U.S. Army and USMC ground forces will be restricted from establishing Intermediate Staging bases (ISBs) and operating within a land based area of operation. The U.S. Air Force, in support of ISR and Strike missions, will be forced to rely on UAVs to mitigate the residual effects of CBRNE agents for an indefinite period of amount of time. The impact of a WMD/CBRNE operating environment to the 2020 JTF is the emphasis on utilizing UMSs throughout the air, land, and sea domains in lieu of manned systems or personnel in order to accomplish its mission. (see Annex A).

Academic Publications

The two prolific academic writers on robotics/unmanned systems and their impact on future military operations are Dr. Robert Finklestein and P.W. Singer. In "*Robotics in Future Warfare*" Dr. Finklestein, President of Robotic Technology Inc, focuses on his rationale for robots in future warfare. The focus is on the "three D's"; dirty, dull, and dangerous operations that robots can assume. Furthermore, those robots are expendable, maneuverable, have a faster response time, indefatigable, autonomous, and incorporate

2921 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

emerging technology which is a far superior option than human Soldiers.[56] In *Wired for War - The Robotics Revolution and Conflict in the 21st Century*, P.W. Singer, Director of the 21st Century Defense Initiative at Brookings Institute, focuses on the ongoing robotic revolution within the Department of Defense and its implications for 21st century warfare, the "dawn of robotic warfare." He further highlighted in his book that with the end of Operation Desert Shield/Storm (ODS) military leaders assumed that the public's tolerance of Vietnam level casualties had dramatically diminished, leading Major General (Retired) Robert H. Scales to state that in the new era of warfare that "dead Soldiers are America's most vulnerable center of gravity."[57] Furthermore, U.S. State Senator John Warner (Virginia), former Senate Armed Services Committee Chairman, went on record to state that "in my judgment this country will never again permit the armed forces to be engaged in conflicts which inflict the level of casualties we have seen historically… so what do you do? You move toward the unmanned type of military vehicle to carry out missions which are high risk in nature." [58]

In November 2011, the Brookings Institute chaired a panel "The Future of Land Wars: Intense, High-Tech, Urban, Coastal" with current and retired Army officers and professional analysts which provide relevant insights for future UMS procurement and employment considerations. Colonel (COL) Gian Gentile, United States Military

2922 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Academy (USMA) history professor, stated that "we should absolutely avoid building a future ground force optimized for wars like Iraq and Afghanistan … future land battlefields demand a ground force built around the pillars of firepower, protection and mobility, moreover, this future ground force needs to be able to move and fight in dispersed, distributed operations."[59] His insight(s) were further expanded on by Lieutenant General (LTG) (retired) Dave Barno, a Senior Fellow for the Center for a New American Security, stating that the " typical land battlefield of 2021 will be a complex, often urbanized environment where battles are often fought inside the dense urban sprawl that increasingly proliferates along the edges of the world's great cities …. enabling small units to reliably leverage networked technology for access to fires, to employ unmanned and robotic adjuncts and operate mobile fighting systems will be a key sector for investment" (see figure 9).[60]

Liberation Army (PLA) strategic focus is to compete equally with the US military in certain areas, such as submarine warfare, space, and cyber warfare. In December 2011, China placed in operation a satellite navigation service that is designed to provide an alternative to the U.S. Global Positioning System (GPS), which will assist the Chinese military to identify, track and strike U.S. ships in the region in the event of armed conflict.[63] The Beidou Navigation Satellite System provides initial positioning, navigation and timing services to China and its surrounding areas.[64] According to the assessment of Professor Tan Kaijia, a weaponry expert with the PLA's National Defense University, "China has made substantial progress in intelligent control systems, precise measuring-controlling systems and computer information processing for military uses."[65]

The development and manufacture of Chinese of unmanned systems over the past 30 years have been often based on U.S. UAV/UCAV concepts (see table 2).

In addition, China has developed anti-access capabilities such as over-the horizon (OTH) radars that can locate and fix U.S. Navy Carrier Strike Groups (see figure 10). This comprehensive development of Chinese anti-access/area-denial (A2/AD) capabilities will mitigate traditional U.S. power projection capabilities such as uncontested deployment of ground forces, aircraft formations in regional airbases, and the uncontested employment of combat aircraft to support ground operations.

In respect to the current OEF operating environment it is relevant to recognize Pakistan's availability, and procurement of UMS, primarily UAVs. Pakistan at the outset of the U.S. Global War on Terrorism (GWOT) requested and was denied UMS platforms

2927 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

by the United States. Therefore, Pakistan engaged in procuring UAV concepts and systems, both domestically and on the international market.

Pakistan entered into a deal with the Italian firm, Selex-Galileo, in order to produce UAV's at their Kamra Air Weapons Complex. The Pakistan Navy acquired rotorcraft drones from foreign sources. The Pakistani Army has pursued partnerships with China, and local manufacturers to continue to develop more advanced platforms within the country.[67] For example, the Burraq is a high endurance/long range (HE/LR) over the horizon armed UCAV aircraft that is being developed in partnership with China (includes weapons development, control systems development, propulsion, airframe, ground control stations).[68]

UMS Commercial Proliferation

> Unmanned aerial vehicles (UAVs) represent one of the brightest, fastest-growing segments in the aerospace and defense industry . . . move beyond strategic reconnaissance and surveillance and into roles previously filled by manned jet fighter aircraft, combat helicopters, and even special operations forces on the ground . . . will provide battlefield situational awareness, fire support from the air, covert surveillance, and applications no one has thought of yet.[69]

The proliferation of UMS has led to the establishment of multinational organizations such as the Association for Unmanned Vehicle Systems International

[67]"Say hello to Pakistan's first domestically produced armed drone: The Burraq UCAV," 5 December 2011, http://www.techlahore.com/2011/12/04/say-hello-to-pakistans-first-domestically-produced-armed-drone-the-burraq-ucav/ (accessed 15 December 2011).

[69]Military and Aerospace Executive Briefing: Unmanned aircraft applications proliferate, and represent one of the few growing markets in an otherwise-shrinking defense budget, http://www.militaryaerospace.com/executive-briefings/2011/unmanned-aircraft-applications-proliferate.whitepaperpdf.render.pdf. (accessed 14 April 2012).

2928 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

AUVSI).[70] In recognition of the impact within the aerospace and defense industry, the AUVSI's Unmanned Systems North America 2012 Symposium at Mandalay Bay Resort & Casino, Las Vegas, Nevada, will feature the latest issues, trends and developments impacting the unmanned systems and robotics community.[71]

In respect to U.S. Defense firms, they have until recently been restricted from generating UAV export revenue due to the Missile Technology Control Regime (MTCR) Category I export control restrictions.[72] These restrictions strongly discourage export of such platforms to Asia and the Middle East. These markets are serviced by foreign UAV manufacturers and exporters such as Israel, Singapore, and South Africa. In response, American UAV manufacturers redesigned their existing military platforms to fall under the far less restrictive MTCR Category II. General Atomics, focusing in Asia and the Middle East, introduced the Predator XP, designed for overseas buyers. In Asia, General Atomics continues to prioritize Predator B sales to Australia, Japan, and South Korea.

Notes on Methodology

The purpose of this section is to highlight the research methodology that will be used to answer the primary research question: Will the 2020 JTF be postured to utilize

[70]The Association for Unmanned Vehicle Systems International (AUVSI) is the world's largest non-profit organization dedicated to the advancement of unmanned systems and robotics–represents 7,000 members and more than 500 corporate members from 60 allied countries involved in the fields of government, industry and academia, at www.auvsi.org.

2929 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

mandated unmanned systems? In chapter 1 the secondary research questions were identified. In chapter 2 the literature associated with the primary and secondary research questions was discussed. The author's intent is to provide a definitive answer for the secondary research questions, within the limitations outlined in chapter 1. Additionally, it's feasible that simply generating a discussion from the secondary research questions to gain an understanding its relevance to the primary research question may be all that is required. With this intent, conclusions will be drawn for each secondary research question. Therefore, a description of the methodology to be used will follow the following framework.

SRQ #1: What future training will be required for the JTF to employ UMSs? The purpose of this question is to gain an understanding and identify future training requirements for the JTF to employ UMS. In order to generate UMS training requirements, DoD in conjunction with the Services must understand the capabilities of UMS and how they will integrate and support operational reach and provide operational access in the JTF area of operations (JOA). These future training requirements will be outlined in chapter 4–conclusions.

SRQ #2: How will the incorporation of robust UMS capability impact the organization of a JTF in 2020? The purpose of this question is to gain an understanding (or identify) the impact on the organization of a JTF with the integration of revolutionary unmanned systems. In order to generate JTF task organization analysis, DoD in conjunction with the Services must understand the capabilities of UMS and what capabilities can be accomplished by UMS in lieu of manned systems.

2930 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Conclusions and Recommendations

In chapter 3, preliminary conclusions will be provided for the secondary research questions; chapter 4 will provide a final conclusion for each secondary research question and the primary research question. Table 3, provides a reference chart of the research methodology.

Table 3. Research Methodology

SRQ	Purpose	Ends	Ways	Means
1. What future training will be required for the JTF to employ UMSs?	Gain an understanding of anticipated future UMS capabilities & required staff training	Training requirements & principal staff directorates identified	Examine Service & Functional Component Commander mission requirements	Review Joint publications; UMS academic publications; Service specific UMS roadmaps; JTF case studies
2. How will the incorporation of robust UMS capability impact the organization of a JTF in 2020?	Identify mission requirements for the JTF and staff directorates in which UMS can be employed in lieu of manned platforms	JTF task organization recommended	Examine Functional Component Commander mission requirements	Review Joint publications; UMS academic publications; Service specific UMS roadmaps; JTF case studies

2931 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER 3

ANALYSIS

The purpose of chapter 3 is to present the findings of the research in order to answer the primary research question: Will the 2020 JTF be postured to utilize mandated unmanned systems? As discussed in Chapter 2, JP 3-33, Joint Task Force Headquarters, outlines the doctrinal framework to establish a JTF HQ and its Functional Component Commands. The understanding of the capabilities, duties, and responsibilities of the staff functions and commands will facilitate the analysis of UMS integration in its operations.

Functional Component Commands

A functional component command is composed of forces of two or more DoD Services in which the Service component commander with the preponderance of forces is designated as the functional component commander (see table 4).

2932 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 4. Functional Component Command Considerations

Source: Created by author using data from Chairman, Joint Chiefs of Staff, Joint Publication (JP) 3-33, *Joint Task Force Headquarters* (Washington, DC: Government Printing Office, 16 February 2007).

Joint Forces Air Component Commander (JFACC)

A JFACC will be designated based on having the preponderance of air assets and the ability to effectively plan, task, and control joint air operations. The responsibilities of the JFACC include, planning, coordinating, and monitoring joint air operations and the allocation and tasking of joint air operations forces.[73] The operational consideration is the integration of UMSs described in Chapter 2 (UAVs will be predominate in the JFACC)

[73]Chairman, Joint Chiefs of Staff, Joint Publication (JP) 3-33, *Joint Task Force Headquarters* (Washington, DC: Government Printing Office, 16 February 2007), III-5.

2933 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

throughout the JFACC subordinate division in lieu of manned systems; primarily the Combat Operations and ISR Division (see figure 11).

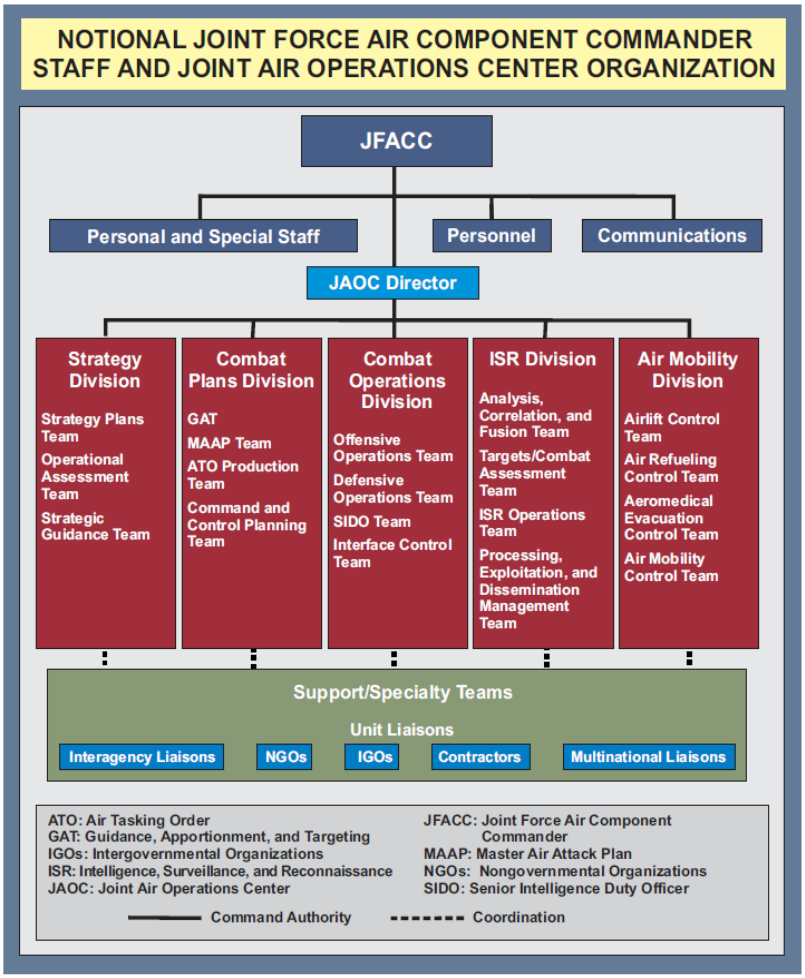

Figure 11. Notional JFACC Composition

2934 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Joint Forces Land Component Commander (JFLCC)

The designation of a JFLCC typically occurs when forces of more than one Service component participate in a land operation and the CJTF determines that doing this will achieve unity of command and effort among land forces.[74] The essential planning consideration for a JFLCC is the availability of ports of debarkation and the mutual support possible between land forces. A JFLCC can consist of an Army corps or MAGTF (see Table 2). The operational consideration is the integration of UMSs described in Chapter 2 (UGVs, UGSs, and UAVs) throughout JFLCC operations in lieu of manned systems and/or personnel.

Joint Forces Maritime Component Commander (JFMCC)

The essential task of a JFMCC is to command and control joint maritime operations. These forces, generally, consist of ship formations, marines and Special Operation Forces (SOF). Typical JMFCC missions include: sea control, maritime power projection, deterrence, strategic sealift, forward maritime presence, and sea basing operations.[75] The operational consideration is the integration of UMSs described in chapter 2 (USVs, UUVs, UAVs) throughout JFMCC operations in lieu of manned systems and/or personnel.

Joint Forces Special Operations Commander (JFSOC)

The JFSOC generally will be the commander with the preponderance of SOF and appropriate command and control structure to conduct operations. Additionally, the

[74]Chairman, Joint Chiefs of Staff, Joint Publication (JP) 3-33, III-7.

[75]Ibid., III-9.

2935 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JFSOC may establish a joint special operations air component commander (JSOACC) responsible for planning and executing joint special operations air activities. This includes the responsibility to coordinate, allocate, task, control, and support the assigned and attached joint special operations aviation assets.[76] The operational consideration is the integration of UMSs described in Chapter 2 (USVs, UUVs, UAVs, UGVs, and UGSs) throughout JFSOC operations in lieu of manned systems and/or personnel.

Joint Task Force Directorates

The operational considerations of UMS integration does not solely rest on the Services as they execute their missions as a functional component command, but, also to the JTF staff. As discussed in chapter 1, the 2020 JTF will be required to leverage cutting-edge information technologies to ensure a secure and collaborative command and control network. These requirements will generate training requirements for the staff to plan and execute operations with UMSs in lieu of manned platforms. A key impact will be on the JTF Chief of Staff (COS) who serves as the key staff integrator. The COS is responsible for the establishment and management of staff processes and procedures that support the JFC decision making process.[77]

The impact to the JTF J2 will be on the Joint Intelligence Support Element (JISE). The JISE is the hub of intelligence activity in the Joint Area of Operations (JOA) which requires persistent awareness and is characterized by net-centric and fused operations. Therefore, the impending UMS training requirements support battle space awareness

[76]Chairman, Joint Chiefs of Staff, Joint Publication (JP) 3-33, III-11.

[77]Ibid., II-8.

2936 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

(BA) and the Tasking, Production, Exploitation, and Dissemination (TPED) process to translate sensor data into a common picture becomes apparent. Furthermore, the projected UMS platforms with their requirement to operate with full autonomy will extend their BA persistence capabilities from days to weeks across all of the domains.

The impact to the J3 will be to support and execute Force Application (FA) missions which are focused on maneuver and engagement. The Joint Operations Center serves as the focal point for all operational matters and the current operations (CUOPS) element is staffed by J-3 air, land, maritime, and special operations watch officers. The projected UMS platforms will be able to assume air, ground, and sea operations in lieu of manned platforms and/or personnel. Additionally, the J3 (Operations Directorate) will need to leverage UMS protection platforms that will assist in FORCEPRO tasks, such as FOB security, obstacle construction/breach, sophisticated explosive ordnance disposal, and casualty extraction and evacuation. The J-4 provides the foundation of combat power, by air, land, and sea. Additionally, the J-4 must understand the capabilities of all UMS mobility assets as they become available throughout sustainment and operations. The discussions of the UMS capabilities across the services support these requirements and require successful integration in order to support the JFC's decision making process and execution of its assigned missions.

Case Studies

> Historically, creating a joint task force (JTF) has come with its share of forming and planning difficulties . Typically, a Service two or three-star headquarters will be designated as the JTF for a crisis or contingency and will receive augmentation from the Services to fill the capability gaps within the JTF. Most situations require JTFs to be established rapidly, and the lag time in

2937 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> receiving augmentation, coupled with the inexperience of augmentees in joint operations, has proven an ineffective and unsuccessful model.[78]

The first case study for this thesis is the designation of the V Corps HQ as Combined Joint Task Force-7 (CJTF-7) for Operation Iraqi Freedom (OIF I/II- June 2003-May 2004). The overall analysis of CJTF-7 is outside the scope of this thesis; the intent is to: (1) analyze the doctrinal guidance that was followed in establishing CJTF-7 in the dominant operating environment for DoD and the Services at the time, and (2) to determine if the lessons observed allow for future considerations in establishing a JTF under a similar operating environment utilizing unmanned systems in lieu of manned systems and/or personnel. Additionally, the JTF Odyssey Dawn (JTF OD) case study will highlight future considerations for integrating and operating from a mobile C2 platform with unmanned systems in lieu of manned systems.

CJTF-7 Background

In April 2003, the commanding general of 1st Armored Division (1AD), Major General (MG) Ricardo Sanchez was designated the commander of V Corps (Germany) and promoted to Lieutenant General (LTG), concurrently while deploying his division (1AD) from Germany to Kuwait. At this point the Combined Forces Land Component (CFLCC) HQ had been designated the responsibility for Phase IV (establish security) operations. On 17 May, V Corps was officially notified of its designation as a CJTF with

[78]Walter E. Carter, Jr, "The Joint Enabling Capabilities Command: A Rarity within the Conventional Force," *Joint Forces Quarterly* 64 (January 2012): 19.

2938 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

a Relief in Place/Transfer of Authority (RIP/TOA) set for 15 June 2003, less than 30 days to prepare for assuming responsibility for all operations in Iraq.[79]

Challenges

The immediate challenges faced by CJTF-7 were to support operations at the tactical, operational and theater strategic level. It was unable to initially do so, due to it being grossly understaffed and lacking strategic communications and capability. The end result, was that it took six to eight months for CJTF -7 to become fully operational and capable (FOC); which was roughly at the 75 percent completion date of its 12 month rotation. In COL (R) Mansoor's assessment "CJTF-7 lacked the link between the strategic ends and tactical means that would ensure a successful outcome."[80] For the foreseeable hybrid-threat environment, six to eight months to become FOC will result in mission failure.

Analysis

For the 2020 JTF assigned to a similar operating environment, UMSs will provide strategic communications, C2, and ISR throughout the phasing of operations; Phase 0 (shape), Phase I (deter), Phase II (seize the initiative), and Phase III (dominate), which will exploit the initiative and dictate the operational tempo. The follow on phases, Phase IV (establish security) and Phase V (enable civil authority) can incorporate UMSs with

2939 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

land forces, providing capabilities normally performed by manned platforms or personnel.

The second case study for this thesis is the designation of the U.S. Navy 6th Fleet as the HQ for JTF Odyssey Dawn in support of operations in Libya.

JTF Odyssey Dawn (Libya) Background

In March 2011, U.S. Africa Command (USAFRICOM) established Joint Task Force Odyssey Dawn (JTF OD) under the command of Admiral Samuel Locklear III, commander of U.S. Naval Forces Europe – Africa, to support United Nations Security Council Resolutions (UNSCRs) 1970 and 1973. The JTF mission was to (1) provide humanitarian assistance, (2) support noncombatant evacuation (NEO) operations, (3) enforcement of a maritime exclusion zone and (4) enforcement of a no-fly zone within the JOA Libya.[81] In the span of three weeks, JTF OD conducted a coalition air campaign against Libya's integrated air defense systems and halted Libyan government forces from advancing against rebel-held population centers. On March 31, JTF OD transferred command and control of the operation to NATO; re-designated as Operation Unified Protector.

Challenges

The JTF was composed of U.S. personnel and foreign liaison officers with additional augmentation with a Joint Deployable Team (JDT) provided by the United States Transportation Command (USTRANSCOM) Joint Enabling Capabilities

[81]JTF Odyssey Dawn website, http://www.naveur-navaf.navy.mil/odysseydawn/index.html (accessed 10 March 2012).

2940 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Command (JECC). The JTF OD staff was headquarted and certified aboard the USN 6th Fleet Command and Control ship the USS Mount Whitney (LCC/JCC 20). The JTF consisted of a JFMCC, JFACC, and JFSOC. A JFLCC was not established. However, a USMC battalion deployed as an Air Contingency Battalion (ACB) to serve as a Battalion Landing Team for the 26th Marine Expeditionary Unit (MEU) in the event landing forces were required throughout JOA Libya. In the conduct of an after action review (AAR) the inclusion of a designated JFLCC was deemed essential for mission planning and force employment.

> JTFs should consider the composition of the adversary when forming its own structure, even if ground troops are not employed on the friendly side. Filling every key position of a JTF staff will enhance understanding of the operational environment and can multiply the effects and outcomes of the planning process and subsequent operation execution. In future operations where U.S. ground forces are not employed, consideration of a JFLCC team to conduct planning and provide input covering some or all of the functions is essential.[82]

Analysis

The JTF OD mission merits further evaluation of future missions that can be assumed by unmanned systems in lieu of manned systems, such as strike coordination and reconnaissance, defined as a mission flown for the purpose of detecting targets and coordinating or performing attack or reconnaissance on those targets (also known as

[82]Gregory K. James, Larry Holcomb, and Chad T. Manske, "Joint Task Force Odyssey Dawn: A Model for Joint Experience, Training, and Education," *Joint Forces Quarterly* 64 (January 2012): 26.

2941 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

SCAR see table 5).[83] Furthermore, UMSs support all the steps of the Dynamic Targeting Steps, such as find, fix, track, target, engage, and assess.[84]

[84]Ibid., 31.

[85]Weapons of Mass Destruction-Elimination (WMD-E) was not a specified task for JTF OD, the implied planning consideration becomes apparent with presence of the Rabta chemical weapons facility, which was estimated to contain 23T of mustard gas and 1,300T of precursor chemicals. WMD elimination operations are actions to systematically locate, characterize, secure, disable, or destroy WMD programs and related capabilities (ATTP 3-11, M*ulti-Service Tactics, Techniques, and Procedures for Weapons of Mass Destruction Elimination Operations*, 10 December 2010, 1-1).

2942 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In summary and comparison, CJTF-7 faced the challenges of (1) unclear mission focus, (2) conflict in levels of authority, (3) inadequate staff augmentation, (4) lack of strategic communications, and (5) an estimated six to seven months for the CJTF to become fully operational & capable (FOC). In comparison, JTF OD provided a mobile platform with (1) mission focus, (2) levels of authority clearly established, (3) critical staff was augmented by the JECC, (4) strategic communications was provided by the JCSE, and (5) the JTF was FOC and completed all assigned tasks within a three week period.

CHAPTER 4

CONCLUSIONS AND RECOMMENDATIONS

Conclusions

The purpose of Chapter 4 is to answer the primary research question; will the 2020 JTF be postured to utilize mandated unmanned systems? In order to answer this question, two secondary research questions have been analyzed.

UMSs have provided great capability throughout operations in OEF /OIF and are being designed to provide exponentially greater capabilities within the next 8-10 years that will dramatically impact the way the 2020 JTF executes its missions (see table 6). This thesis did not cover the broad spectrum of UMS development which ranges from nanotechnology (machines that are the size of a hummingbird, or smaller) utilizing SWARM technology to unmanned submarines. This thesis only covered the time period from the present to the year 2020, a period of eight years. The Service UMS Roadmaps extend beyond 2030 and to speculate about the capabilities that will become available in the next 18 years is beyond the scope of this thesis. Furthermore, excluded were numerous academic institutions, such as the Stanford Research Institute (Robotics and Artificial Intelligence Center), Florida Institute for Human and Machine Cognition, and QinetiQ that actively engage with DoD R&D and continue to expand on the estimated 7,000 unmanned/robot systems that are being utilized throughout the Global War on Terrorism.

Table 6. UMS Technology Roadmap (2012-2020)

		2012	2020	
Interoperability	Technology	Common Data links & Encryption	Common data standards across all services and platforms	Synergistic operation through the exchange, interpretation and action on data from coalition systems
	Capability	Common ground stations	Common autonomy capabilities across platforms	
Autonomy	Technology	Multi-sensor data fusion	Intelligent control	Force structure reduction and full, reliable autonomous control during complex mission sets
	Capability	Environmental understanding and adaptation	Autonomous collaboration	
Airspace Integration	Technology	Ground based Sense and Avoid	Airborne Sense and Avoid	UAS unfettered access to national and international airspace
	Capability	Missions in low density airspace	Dynamic operations for Medium and Large UAS	
Training	Technology	High Fidelity Simulators/Trainers	Universal Ground Control Station	TBD
	Capability	Manned/Unmanned Teaming	Universal Pilots and Operators	
Manned-Unmanned Teaming	Technology	UAV FMV and target data to manned aircraft	Cognitive machine learning	TBD
	Capability	MUMT-2 (air to air to ground)	Unmanned scout and attack	

Source: Department of Defense, *Unmanned Systems Integrated Roadmap FY2011-2036* (Washington, DC: Government Printing Office, October 2010), 89.

The impact for DoD and pertinent for this thesis is how will these revolutionary systems impact the DOTMLPF process, more specifically the 2020 JTF. At which echelon will there be a centralized entity to integrate these unmanned systems and operational capabilities for the 2020 JTF? Will these occur at the Geographic Combat Commander (GCC) level, or with the Service Component Commands who will then

2945 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

advise the GCC upon establishing a JTF? With the consensus that the future operating environment will be hybrid, which includes A2/AD threats, the emphasis for establishing a fully operational and capable (FOC) based on the JTF OD model, mitigating the CJTF-7 operational challenges, becomes a further opportunity for Senior leadership to consider: "jointness is not automatic; it must be continually updated through joint integrated joint force development activities to provide relevant capabilities that are responsive to the security environment."[86]

The establishment of a UMS consolidated proponency within an appropriate CJCS directorate, such as the J7/ Joint Force Development and Integration (JFDID) division should be considered. The JFDID serves as the primary agent for developing and monitoring the implementation plans for joint experimentation and concept development.[87] Additionally, the USSTRATCOM Joint Functional Component Command for Intelligence, Surveillance and Reconnaissance (JFCC-ISR) merits consideration. The JFCC-ISR is responsible for aligning processing, exploitation, and dissemination (PED) capacity with ISR allocation to provide enablers necessary to deliver intelligence to combatant command. This recommendation is based on that all UMSs primarily serve as an ISR platform which can be re-configured to strike platforms.

All leaders and organizations that can directly impact UMS integration must support a culture of innovation, emphasizing the capabilities provided by these unmanned

[86]Joint Forces Quarterly, "Joint Doctrine Update," *JFQ* 64 (1st Quarter 2012): 148.

[87]The author makes this recommendation based on the availability of unclassified sources. A discussion on the dissolution and capabilities of U.S. Joint Forces Command is outside the scope of this thesis.

2946 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

systems throughout their formations. Therefore, the author offers a relevant outline from General (retired) Don A. Starry who found himself in a similar period of transformation, which required him to "bring clearly a focused intellectual activity in the matter of any change."[88] In this case, the integration and employment of UMSs in lieu of manned systems or personnel throughout military operations.

1. There must be an institution or mechanism to identify the need for change.
2. There must be a spokesperson for change.
3. The spokesperson must build consensus amongst a wide audience.
4. There must continuity among the architects of change.
5. Changes proposed must be subjected to trials to determine their relevance.

All of the above have been presented throughout this thesis. For example, the mechanism for change has been identified as the FY2001 NDAA. The spokesman for change has been identified as academic writers and organizations, such as P.W. Singer and the AUVSI. The spokesman who must build consensus is present within the U.S. Congress, such as Congressman Howard P. "Buck" McKeon (R-CA), Chairman of the Congressional Unmanned Systems Caucus (CUSC), which recognizes the overwhelming value of unmanned systems in the scientific, intelligence, law enforcement, and homeland security communities.[89] Additionally, consensus is needed within the U.S. House Robotics Caucus which focuses on: (1) educating members of Congress and

[88]GEN (R) Don A. Starry, "To Change an Army," *Military Review* 63, no. 3 (March 1983): 20-27. This article is adapted from an address made by GEN Starry, 10 June 1982, to the US Army War College Committee on a Theory of Combat, Carlisle Barracks, PA. CGSC Copyright Registration #11-270 C/E.

2947 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

congressional staff on current & future research and development, and utilization initiatives and (2) ensure that the nation remains globally competitive as the robotics industry expands and further affects the way we live our lives.[90] The continuity amongst the architects of change is reflected in the Services UMS roadmaps, many of which extend well beyond the timeline discussed in this thesis. Finally, the changes proposed must be subjected to trials to determine that their relevance is present in the DoD R&D directorates and amongst the commercial industry trials/programs that have been highlighted in this thesis.

Secondary research question conclusions

SRQ #1: What future training will be required for the JTF to employ UMSs?

In the DOTMLPF analysis process, *training* examines how we prepare our forces to fight and determine methods of improvement to offset war fighting capability gaps. It addresses the following questions: (1) is the issue caused by lack of or inadequate training? (2) does training exist which addresses the issue? and (3) do personnel affected by the issue have access to training?

Analysis of these questions reveals that the Services each participate in collective training throughout their respective training centers. The U.S. Army Combat Training Centers (CTC) offer the opportunity to fully integrate the UMS platforms outlined in this thesis to support the Army's Operating Concept; specifically, combined arms maneuver and wide-area security (CAM/WAS). Additionally, the Joint Multinational Readiness

[90]U.S. House Robotics Caucus, http://www.roboticscaucus.org/.

2948 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Center (JMRC) in Grafenwoehr, Germany allows for the integration of U.S. and Coalition UMS programs and training.

The U.S. Navy's participation in a fleet exercise/joint task force exercise (FLEETEX/JTFEX) requires that it integrate all its forces in a multi-dimensional, multi-threat environment, in which UMS can range from UAVs, USVs, UUVs, and UGSs. In this respect, a JTFEX allows all participants to train with emerging systems and technology, such as UMS.

The U.S. Air Force engages in counter-UAV(C-UAV) scenarios, such as, Black Dart, Blue Knight, and Red Flag. The purpose of Black Dart is to determine DoD's ability to detect and counter enemy UAS systems in flight.[91] The purpose of Blue Knight is to simulate air to air combat between UAVs, which due to the proliferation of UAVs is a realistic expectation in the near future and an operational concern for the 2020 JTF.[92] The feasibility of Red Flag exercises extends to training USAF pilots in fighter interdiction, attack, defense suppression, airlift, air refueling, and reconnaissance.[93] The majority of these missions have been determined capable of being assumed by UAVs by the USAF *Unmanned Aircraft Systems Flight Plan 2009-2047* in lieu of manned systems.

2949 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In respect to the case studies and for future JTF operational considerations, a critical component for JTF OD was provided by the Joint Enabling Capabilities Command (JECC/USTRANSCOM). The JECC is a collection of high-demand joint capabilities ready to immediately support joint force commander requirements worldwide. The JECC provides mission-tailored, ready joint capability packages to Combatant Commanders in order to facilitate the rapid establishment of Joint Force Headquarters and to fulfill Global Response Force Execution and Bridge Joint Operational requirements.[94]

The two critical enablers provided by the JECC were a Joint Deployable Team (JDT) consisting of experienced joint planners in planning and execution of the full range of joint military operations. Additionally, they provided expertise in operations, plans, knowledge management, intelligence, and logistics. Second, a Joint Communications Support Element (JCSE) delivered secure, reliable, and scalable command, control, communications, and computer (C4) capabilities to JFC's, U.S. Special Operations Command, and other agencies. The JSCE provided essential C4 support, ranging from small mobile teams to full-sized JTF headquarters that immediately establish and then expanded the communications capability of a JTF headquarters. Furthermore, the JCSE can access the full range of DoD and commercial networks.[95]

SRQ #2: How will the incorporation of robust UMS capability impact the organization of a JTF in 2020?

---

[94]Department of the Army, United States Transportation Command, JECC, http://www.transcom.mil/jecc/ (accessed 5 February 2012).

[95]Ibid.

2950 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In the DOTMLPF analysis process, *organization* examines how we are organized to fight and if there is a better organizational structure or capability that can be developed to solve a capability gap. It addresses the following questions: (1) where is the problem occurring?, (2) what is the mission focus of those organizations?, and (3) are Senior leaders aware of the issues?

Analysis of this question reveals that the Services are incorporating the organizational changes to incorporate UMS with the end state to reduce personnel/logistical footprints and exponentially enhance its operational capabilities. The USAF has established a robust Remote Piloted Aircraft (RAP) program for its officers, to include a career field and UAV formations. The USN is engaged in UMS programs that have strategic implications, such as strategic forward presence. The United States Marine Corps is restructuring their MAGTF to incorporate UMSs. The U.S. Army is primarily focusing on UGVs and UAVs to support future land operations. The challenge for Senior leaders, both military and civilian, is the integration of UMSs and its reduced personnel footprint to support the 2020 JTF. The experience of a JTF HQ taking almost eight months to become fully operational& capable (FOC) is not an option. The capabilities of UMS have the ability to reduce the length of operations from months to weeks.

Answer to the Primary Research Question

So, will the 2020 JTF be postured to utilize revolutionary unmanned systems? At this time all available information to the author indicates that the 2020 JTF will have the basic organizational framework to incorporate unmanned systems. Additionally, the services have initiated the organizational changes to integrate UMSs with the understanding that an end state is for these systems to reduce the personnel and logistical

2951 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

footprints throughout military operations. However, at this time, unclassified sources have not provided a definitive answer to the integration of UMSs to support the 2020 JTF. The CJCS has directed the Services with a specified and essential task; the 2020 JTF will be required to leverage cutting-edge information technologies to ensure a secure and collaborative C2 network in an operational environment encompassing hybrid threats, A2/AD threats, and the proliferation of advanced unmanned systems. The CJTF -7 case study highlighted lessons observed that cannot be repeated in establishing a JTF in the future operating environment in order to accomplish the specified task(s) outlined by the CJCS. Additionally, the JTF OD case study highlights the future considerations of integrating UMS to accomplish missions traditionally executed by manned platforms and/or personnel.

Recommendations

The 2020 JTF will be postured to utilize revolutionary unmanned systems, if the following recommendations are implemented:

1. Establish a Joint UMS Directorate to assist combat commanders in the integration and training of a JTF utilizing the aforementioned UMSs. Additionally, this UMS directorate would establish an UMS Lexicon that would provide a common language and end the debate of how to properly classify an UMS platform, for example is a Reaper an UAV or UAS? The current ALFUS document provides a starting point on codifying a DoD UMS Lexicon which can be adopted by other government, civilian, and academic organizations.

2. Services must continue to leverage their respective training centers and exercises to fully exploit the incorporation of UMSs throughout their operations and

2952 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

provide recommendations to the CJCS on how to best integrate UMS platforms and formations within the 2020 JTF. For example, the U.S. Army is currently conducting discussions on the future task organization of its Battlefield Surveillance Brigade (BfSB) which provides ISR to the supported Division commander and higher echelons. The ability to integrate UAS, UGV and UGS (Unattended Ground Sensors) will exponentially increase the ISR capabilities for the commander while reducing the personnel and logistical requirements; to include mitigate AD/A2 threats.

3. DoD must encourage a culture of innovation with specific emphasis on UMS throughout all of its echelons. As UMSs continue to develop it capacity for autonomy and replace manned systems and personnel, leaders must consider the new tactical and operational capabilities these systems provide. It can be argued that at the tactical level, U.S. Service members readily adapt, however, military organizations as a whole are often deliberate to accept change due to the invested time and resources in supporting their respective Services strategic considerations. Additionally, DoD must encourage institutional training on UMS which can dissuade potential Service hindrance to change and allow for discourse amongst leaders regarding the impact of UMS integration into their respective Services and for the 2020 JTF.

4. DoD expands the capabilities of organizations, such as the JECC, to train Joint officers on the incorporation and execution of staff processes utilizing UMSs. The notional JTF HQ structure will likely remain the same; however, as UMSs reduce mission accomplishment from months to weeks, the feasibility of an organization such as the JECC becomes apparent. An end state for UMS incorporation throughout the Services is the reduction of personnel/formation footprint throughout its operations.

2953 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Therefore, DoD must continue to support UMS development, and specific to this thesis to ensure that the 2020 JTF is postured to integrate and accomplish its essential tasks utilizing unmanned systems in lieu of manned platforms.

Recommendations for further research

While the aforementioned recommendations are of most importance, there continues to be room for further discussion and analysis on this ever-evolving topic. These topics and areas for further research include (1) UMSs impacts all three levels of war, (2) the Services doctrinal framework, (3) continuing impact to the DOTMLPF process, and (4) impact on Joint, Interagency, Intergovernmental, and Multinational (JIIM) planning considerations and integration.

2954 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

GLOSSARY

Air interdiction. Air operations conducted to divert, disrupt, delay, or destroy the enemy's military surface capabilities before it can be brought to bear effectively against friendly forces, or to otherwise achieve objectives that are conducted at such distances from friendly forces that detailed integration of each air mission with the fire and movement of friendly forces is not required (Joint Publication 3 -03, Joint Interdiction, 14 OCT 2011, GL-4).

Cognizance Levels or Levels of Cognizance. The levels of what a UMS can know or understand based on its sensory processing capability: Level 1. Data or observed data, initially processed forms after measured by sensors. Level 2. Information, further processed, refined and structured data that is human understandable. Level 3. Intelligence, knowledge, combat and actionable information. Further processed for particular mission needs. Directly linked to tactical behaviors.

Common Operational Picture (COP). A single identical display of relevant information shared by more than one command; to facilitate collaborative planning and situational awareness.

Cooperative Engagement. A method of engagement for destroying enemy forces, employing sensors and shooters not resident on the same platform.

Controlling Element. The part of a UMS that provides a method for a human to control it remotely.

Information Superiority. Information, information processing, and communications networks are at the core of every military activity. The development of a concept labeled *the global information grid* (GIG) will provide the network-centric environment required to achieve this goal. Interoperability is the foundation of effective joint, multinational, and interagency operations, a mandate for the joint force of 2020 especially in terms of communications, common logistics items, and information sharing. Information systems and equipment that enable a common relevant operational picture must work from shared networks.

Markers. (physical or electronic). A visual or electronic aid used to mark a designated point for such tactical purposes as route following, determination of bearings, courses, or location, and key items or points of interest, including landmine markers, minefields markers, and area NBC decontamination markers.

Material Solution. Correction of a deficiency, satisfaction of a capability gap, or incorporation of new technology that results in the development, acquisition, procurement, or fielding of a new item (including ships, tanks, self-propelled weapons, aircraft, etc., and related software, spares, repair parts, and support equipment, but excluding real property, installations, and utilities) necessary to equip, operate, maintain, and support military activities without disruption as to

2955 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

its application for administrative or combat purposes. In the case of family of systems and system of systems approaches, an individual materiel solution may not fully satisfy a necessary capability gap on its own.

Non-materiel solution. Changes in doctrine, organization, training, materiel, leadership and education, personnel, facilities, or policy (including all human systems integration domains) to satisfy identified functional capabilities. The materiel portion is restricted to commercial or non-developmental items, which may be purchased commercially, or by purchasing more systems from an existing materiel program. The materiel portion must comply with all acquisition policies.

Operator Control Unit (OCU). Also referred to as operator control interface (OCI) or human interaction control unit. The computer(s), accessories, and data link equipment that an operator uses to control, communicate with, receive data and information from, and plan missions.

Precision Engagement. The effects based engagement that is relevant to all types of operations. Its success depends on in-depth analysis to identify and locate critical nodes and targets. The pivotal characteristic of precision engagement is the linking of sensors, delivery systems, and effects.

Point and Shoot. A subset of cooperative engagement that allows a soldier or platform to designate a target for lethal engagement by another platform. The information is immediately displayed on the COP. Point and Shoot implies the immediacy of effects and generally occurs within the same echelon.

Remotely Guided. An unmanned system requiring continuous input for mission performance is considered remotely guided. The control input may originate from any source outside of the unmanned system itself. This mode includes remote control and teleoperation.

Sensor to Shooter. The information link from a target acquisition capability to the weapons platform(s) that engage(s) the target.

Standoff. Detection or lethality efforts intended to suppress an enemy threat from a position outside the range of the enemy threat.

Unattended Ground sensors (UGS). Small, low cost, robust sensors, capable of operating in the field for extended periods of time (30 days or more). They will consist of modular groups of sensors utilizing tailorable ground sensing technologies, such as seismic, magnetic, infrared, acoustic, radio frequency, and CBRN detection, and other advanced sensing capabilities. UGSs self-organize into a networked sensor array (sensor web) by locating the most efficient gateways for transmission of information.

MA6-B	Perform advanced manufacturing: metal lithography	1	1	2	4	No	1 = High (> 5 years)	1 = High (> $10M)	2 = Mid

2957 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

APPENDIX B

Interoperability across UMS Domains Vignette, 2030s Scenario

1. a. A former Soviet-era, *Akula* class, nuclear-powered attack submarine sails out of a rouge state undetected by reconnaissance satellites and detected by a US Navy underwater surveillance grid, triggering an unmanned underwater vehicle (UUV) to deploy and tether itself to the submarine.

1. b. Every three hours the UUV transmits a low-power position report which is received by an orbiting communications relay, the Baton One, an EQ-25 (UAS) operating at 75,000 ft. The EQ-25 is an extreme-endurance UAS, capable of operating for two months on station without refueling.

1. c. By the third day of sail, the submarine is heading toward the mid-Pacific and the Hawaiian Islands. The decision is made to deploy a naval anti-submarine warfare (ASW) ship to intercept and track the submarine. The following day, the submarine reverses course and the ASW ship turns for Pearl Harbor.

1. d. A Broad Area Maritime Surveillance (BAMS) UAS, MQ-4C, is launched from Guam to in order to track the beacon. Autonomously descending with its internal airborne sense and avoid (ABSAA) system the BAMS UAS is able to visually acquire the UUV, detached from the submarine. The submarine's position and intent are now unknown.

1. e. Ten days later, seismic disturbances are detected 150 miles southeast of Anchorage, Alaska. An interagency DoD/homeland defense reconnaissance UAS is launched and detects a radiation plume. The UAS maps the plume as it begins spreading over the sound, and a U.S. Coast Guard offshore patrol cutter employs its unmanned helicopter to drop buoys with CBRN sensors to measure fallout levels. The plume begins to spread over the sound and threatens the city of Valdez. The port of Valdez, the largest indigenous source of oil for the United States, is effectively under quarantine.

1. f. Due to the growing contamination of the local environment, disaster response officials request US military unmanned CBRNE support. The amphibious transport dock ship USS *New York* anchors near an entrance to Prince William Sound and begins

2958 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

operations with its unmanned surface vehicles (USVs) and MQ-8 Fire Scout unmanned helicopters. An EQ-25 orbit is established over the Sound to ensure long term, high-volume communication capability in the high-latitude, mountainous region. The EQ-25 UAS is capable of handling all the theater data relay requirements.

1. g. A USV proceeds to the focus of contamination and lowers a tethered remotely operated vehicle (ROV) to conduct an underwater search for the source and finds the open hull of the *Akula* class submarine. The ROV places temperature gradient sensors on the hull and inserts gamma sensors into the exposed submarine compartments.

1. h. The radiation plume has now encompassed the evacuated town of Valdez, and MQ-8 Fire Scout fly repeated sorties to the town, dock, and terminal areas to deploy unmanned ground vehicles (UGVs) with sensors and collect samples for analysis.

1. i. With conditions deteriorating, two unmanned Homeland Defense CBRN barges fitted with cranes, containers, and remote controls arrive from Seattle. Over the next two weeks, ROVs equipped with cutting torches, grappling fixtures, and operating from USVs, one remotely operated submersible barge is able to work around the clock and recover the exposed fuel sources and to isolate them in specially designed containers. A second barge similarly retrieves sections of the crippled submarine. Both barges operate with a high degree of autonomy, limiting exposure of personnel to the radioactive contamination.

1. j. The UGVs continue monitoring contamination levels and collecting samples, but now also start conducting decontamination of the oil terminal control station and the local power and water facilities. Highly contaminated soil is placed into steel drums, and larger UGVs are used to dig pits and bury contaminated building and pipeline materials.

1. k. Advanced sensor technology and control logic allows the UGVs to operate around the clock with human operators serving solely in a monitoring function. USVs are used to collect carcasses floating in the Sound and bring them to shore for disposal. UASs fly continuously at low altitude to monitor and map the declining radiation contours, at medium altitude to map cleanup operations, and at high altitude to relay control commands and data from the nearly one hundred unmanned vehicles at work.

2959 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

1. l. Decontamination, refueling, and repair shops have been established in nearby Cordova to service the vehicles and aircraft and on the USS *New York* to service the boats and submersibles, thereby, conducting the largest demonstration of interoperability between air, ground, and maritime unmanned systems.[96]

[96]This vignette offers an example of the increased capability and flexibility inherent in unmanned systems as DoD continues to field unmanned technologies and integrate resulting systems into its existing force structure. Adopted from the U.S Department of Defense, *The Unmanned Systems Integrated Roadmap*, *FY 2011 -2036,* 6.

Form Approved
OMB No. 0704-0188

Public reporting burden for the collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204, Arlington VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to a penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.

Summary

Unmanned aerial systems comprise a rapidly growing portion of the military budget, and have been a long-term interest of Congress. At times, Congress has encouraged the development of such systems; in other instances, it has attempted to rein in or better organize the Department of Defense's efforts.

Unmanned aircraft are commonly called unmanned aerial vehicles (UAVs), and when combined with ground control stations and data links, form UAS, or unmanned aerial systems.

The use of UAS in conflicts such as Kosovo, Iraq, and Afghanistan, and humanitarian relief operations such as Haiti, revealed the advantages and disadvantages provided by unmanned aircraft. Long considered experimental in military operations, UAS are now making national headlines as they are used in ways normally reserved for manned aircraft. Conventional wisdom states that UAS offer two main advantages over manned aircraft: they are considered more cost-effective, and they minimize the risk to a pilot's life. For these reasons and others, DOD's unmanned aircraft inventory increased more than 40-fold from 2002 to 2010.

UAVs range from the size of an insect to that of a commercial airliner. DOD currently possesses five UAVs in large numbers: the Air Force's Predator, Reaper, and Global Hawk, and the Army's Hunter and Shadow. Other key UAV developmental efforts include the Air Force's RQ-170 Sentinel, the Navy's Unmanned Carrier-Launched Airborne Surveillance and Strike (UCLASS), MQ-8 Fire Scout, and Broad Area Maritime Surveillance (BAMS) UAV, and the Marine Corps's Small Tactical Unmanned Aerial System.

In the past, tension existed between the services' efforts to acquire UAS and congressional initiatives to encourage a consolidated DOD approach. Some observers argue that the result has been a less than stellar track record for UAS programs. However, reflecting the growing awareness and support in Congress and the Department of Defense for UAS, investments in unmanned aerial vehicles have been increasing every year. DOD spending on UAS has increased from $284 million in FY2000 to $3.3 billion in FY2010.

Congressional considerations include the proper pace, scope, and management of DOD UAS procurement; appropriate investment priorities for UAS versus manned aircraft; UAS future roles and applications; legal issues arising from the use of UAS; issues of operational control and data management; personnel issues; industrial base issues; and technology proliferation.

Background

Since 1917, United States military services have researched and employed unmanned aerial vehicles (UAVs).[1] Over that time, they have been called drones, robot planes, pilotless aircraft, RPVs (remotely piloted vehicles), RPAs (remotely piloted aircraft) and other terms describing aircraft that fly under control with no person aboard.[2] They are most often called UAVs, and when combined with ground control stations and data links, form UAS, or unmanned aerial systems.

The Department of Defense (DOD) defines UAVs as powered, aerial vehicles that do not carry a human operator, use aerodynamic forces to provide vehicle lift, can fly autonomously or be piloted remotely, can be expendable or recoverable, and can carry a lethal or nonlethal payload. Ballistic or semi-ballistic vehicles, cruise missiles, and artillery projectiles are not considered UAVs by the DOD definition.[3] UAVs are either described as a single air vehicle (with associated surveillance sensors), or a UAV system (UAS), which usually consists of three to six air vehicles, a ground control station, and support equipment.

Although only recently procured in significant numbers by the United States, UAS were first tested during World War I, although not used in combat by the United States during that war. Indeed, it was not until the Vietnam War that the U.S. employed UAS such as the AQM-34 Firebee in a combat role. The Firebee exemplifies the versatility of UAS—initially flown in the 1950s as an aerial gunnery target and then in the 60s as an intelligence-collection drone, it was modified to deliver payloads and flew its first flight test as an armed UAV in 2002.[4]

The military use of UAS in conflicts such as Kosovo (1999), Iraq (since 2003), and Afghanistan (since 2001) has illustrated the advantages and disadvantages of unmanned aircraft. UAS regularly make national headlines as they perform tasks historically performed by manned aircraft. UAS are thought to offer two main advantages over manned aircraft: they eliminate the risk to a pilot's life, and their aeronautical capabilities, such as endurance, are not bound by human limitations. UAS also protect the lives of pilots by performing those dull, dirty, or dangerous missions that do not require a pilot in the cockpit. UAS may also be cheaper to procure and operate than manned aircraft. However, the lower procurement cost of UAS can be weighed against their greater proclivity to crash, while the minimized risk to onboard crew can be weighed against the complications and hazards inherent in flying unmanned vehicles in airspace shared with manned assets.

UAS use has increased for a number of reasons. Advanced navigation and communications technologies were not available just a few years ago, and increases in military communications satellite bandwidth have made remote operation of UAS more practical. The nature of the Iraq and Afghanistan wars has also increased the demand for UAS, as identification of and strikes against targets hiding among civilian populations required persistent surveillance and prompt

strike capability, to minimize collateral damage. Further, UAS provide an asymmetrical—and comparatively invulnerable—technical advantage in these conflicts.

For many years, the Israeli Air Force led the world in developing UAS and tactics. U.S. observers noticed Israel's successful use of UAS during operations in Lebanon in 1982, encouraging then-Navy Secretary John Lehman to acquire a UAS capability for the Navy. Interest also grew in other parts of the Pentagon, and the Reagan Administration's FY1987 budget requested notably higher levels of UAS funding.[5] This marked the transition of UAS in the United States from experimental projects to acquisition programs.

Initial U.S. capabilities came from platforms acquired from Israel. One such UAS, Pioneer, emerged as a useful source of intelligence at the tactical level during Operation Desert Storm, when Pioneer was used by Navy battleships to locate Iraqi targets for its 16-inch guns. Gulf War experience demonstrated the potential value of UAS, and the Air Force's Predator was placed on a fast track, quickly adding new capabilities.[6] Debuting in the Balkans conflict, the Predator performed surveillance missions such as monitoring area roads for weapons movements and conducting battle damage assessment. Operations in Iraq and Afghanistan have featured the Air Force's Global Hawk, as well as adding a new mission that allows the Predator to live up to its name—armed reconnaissance.

Reflecting a growing awareness and support for UAS, Congress has increased investment in unmanned aerial vehicles annually. The FY2001 investment in UAS was approximately $667 million. For FY2012, DOD has asked for $3.9 billion in procurement and development funding with much more planned for the outyears.[7] DOD's inventory of unmanned aircraft increased from 167 to nearly 7,500 from 2002 to 2010.[8]

DOD's UAS research and development (R&D) funding has also grown, for a variety of reasons: UAS are considered a growth industry, many UAS are relatively inexpensive to produce and new technology in miniaturization has helped accelerate the development of many UAS types.

Congress has approached UAS development with strong encouragement tempered with concern. Notably, in 2000, Congress set the goal of making "one-third of the aircraft in the operational deep strike force aircraft fleet" unmanned.[9] Congress has also directed the formation of joint program offices to ensure commonality among the services' UAS programs. Following expressed concern that DOD's "growing enthusiasm may well lead to a situation in which there is no clear

path toward the future of UAS," Congress also required DOD to submit a UAS roadmap.[10] In some instances, Congress has chastened DOD for what it saw as a leisurely rate of UAS acquisition and encouraged it to speed up this pace, or speed up the incorporation of certain capabilities. For example, an 1996, the House Armed Services Committee (HASC) supported legislation directing DOD to weaponize both the Predator and Hunter, but DOD opposed the initiative.[11]

Although this report focuses on the military uses of UAS, Congress's interest in UAS extends beyond the defense committees, as UAS capabilities have also led to their use in missions outside the military. The Department of Homeland Security operates UAS to help patrol U.S. borders, and Congress has questioned the efficacy of such operations.[12] Further, the use of UAS in a variety of roles, but particularly as platforms for delivering lethal force, raise a number of legal issues of interest to Congress.

Why Does the Military Want UAS?

> In today's military, unmanned systems are highly desired by combatant commanders for their versatility and persistence. By performing tasks such as surveillance; signals intelligence (SIGINT); precision target designation; mine detection; and chemical, biological, radiological, nuclear (CBRN) reconnaissance, unmanned systems have made key contributions to the Global War on Terror.[13]

To be sure, manned systems could accomplish many if not all of the same goals. But "unmanned systems reduce the risk to our warfighters by providing a sophisticated stand-off capability that supports intelligence, command and control, targeting, and weapons delivery. These systems also improve situational awareness and reduce many of the emotional hazards inherent in air and ground combat, thus decreasing the likelihood of causing civilian noncombatant casualties."[14] "UAVs have gained favor as ways to reduce risk to combat troops, the cost of hardware and the reaction time in a surgical strike"[15] and "to conduct missions in areas that are difficult to access or otherwise considered too high-risk for manned aircraft or personnel on the ground."[16]

2976 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

As a result, "The number of platforms in this category—R/MQ-4 Global Hawk-class, MQ-9 Reaper, and MQ-1 Predator-class unmanned aircraft systems (UAS)—will grow from approximately 340 in FY 2012 to approximately 650 in FY 2021."[17]

Some in the military also tout UAS's reduced cost of acquisition and operation when compared to manned platforms. However, the Congressional Budget Office cautions that savings cannot be taken for granted:

> Unmanned aircraft systems are usually less expensive than manned aircraft. Initial concepts envisioned very low-cost, essentially expendable aircraft. As of 2011, however, whether substantially lower costs will be realized is unclear. Although a pilot may not be on board, the advanced sensors carried by unmanned aircraft systems are very expensive and cannot be viewed as expendable ... Moreover, excessively high losses of aircraft can negate cost advantages by requiring the services to purchase large numbers of replacement aircraft.[18]

What Missions Do UAS Currently Perform?

Intelligence, Surveillance and Reconnaissance

Intelligence gathering is UAS' traditional mission. In the 1960s, autonomous drones were used for reconnaissance in the Vietnam War and on strategic reconnaissance missions over denied areas. Early modern controllable UAS were used to loft cameras to allow units in the field to observe opposing forces beyond direct line of sight. Subsequently, longer-endurance systems introduced the ability to maintain surveillance on distant and moving targets.

Strike

The first UAS were essentially unpiloted bombs, designed to fly in a particular direction until the fuel ran out, at which point the entire aircraft would plunge to the ground. Today, some UAS carry precision-guided weapons to attack ground targets, and more are being weaponized, although this is still adding strike capability to systems originally designed for reconnaissance.

A separate class of UAS is being designed from the ground up to carry out combat missions. Called unmanned combat air vehicles, or UCAVs, these systems feature greater payload, speed, and stealth than current UAS.

What Other Missions Might UAS Undertake in the Future?

Resupply

The Navy is investigating how UAS could deliver cargo to ships at sea,[19] and the Marine Corps has awarded contracts to two firms to demonstrate how UAS might resupply units in Afghanistan.[20]

Combat Search and Rescue

Early research is underway to develop the capability for an unmanned system to locate and possibly evacuate personnel behind enemy lines.

Refueling

Large UAS could eventually take on the aerial refueling task now performed by KC-10 and KC-135 tanker aircraft. Tanker flight profiles are relatively benign compared to many others, and they tend to operate far from enemy air defenses. Except for operating the refueling boom (to refuel Air Force aircraft), the refueling crew's primary job is to keep the aircraft flying straight, level, and at a steady speed. In July, 2010, the Defense Advanced Research Projects Agency awarded a contract to demonstrate refueling by Global Hawk UAVs,[21] [22] and a March, 2011 test demonstrated the Global Hawk's ability to receive refueling autonomously.[23] The Global Hawk's 2001 trans-oceanic flights (from the United States to Australia and from the United States to Portugal) demonstrate the ability of current UAVs to fly missions analogous to aerial refueling missions. This same technology could allow UAVs to refuel manned aircraft. The second X-47B will be equipped to demonstrate refueling.[24]

Air Combat

A more difficult future task could be air-to-air combat. Although UAS offensive operations to date have focused on ground targets, UCAVs are being designed to carry air-to-air weapons and other systems that may allow them to undertake air superiority missions. DOD is experimenting with outfitting today's UAVs with the sensors and weapons required to conduct such a mission. In fact, a Predator has reportedly already engaged in air to-air combat with an Iraqi fighter aircraft. In March, 2003 it was reported that a Predator launched a Stinger air-to-air missile at an Iraqi

MiG before the Iraqi aircraft shot it down.[25] While this operational encounter may be a "baby step" on the way toward an aerial combat capability, newer UAS such as the X-47B, Avenger, and Phantom Ray are not being designed with acknowledged air-to-air capability.

In short, UAS are expected to take on every type of mission currently flown by manned aircraft.

Why Are There So Many Different UAS?

Although UAS have a long history, only in the last 10-15 years have advances in navigation, communications, materials, and other technologies made a variety of current UAS missions possible. UAS are therefore still in a period of innovation, both in their design and how they are operated. This can be seen as analogous to military aircraft in the 1930s and 1940s, when technologies and doctrines evolved at a rapid rate to exploit the new technology, and also to the early Jet Age, when the military acquired many different models of aircraft with varying capabilities before settling on a force made up of large numbers of relatively few models based on lessons learned.

Also, the period of UAS innovation has coincided with ongoing US combat operations in Iraq, Afghanistan, and elsewhere. Demand for UAS capabilities in the field is essentially unconstrained.[26] As new systems and capabilities have emerged, the availability of urgent-needs funding has allowed commanders to bring the latest technology into theater without lengthy procurement processes. Thus, instead of traditional competitions in which systems may be tested against each other in advance of operations, new UAS have been deployed directly to the field, where U.S. forces are able to experiment with and exploit their capabilities. The combination of funding, demand, and technological innovation has resulted in DOD acquiring a multiplicity of systems without significant effort to reduce the number of systems or consolidate functions across services.

> For example, the Office of the Secretary of Defense (OSD) is concerned that the Army and Air Force are unnecessarily developing two different electro-optical and infrared sensor payloads for Sky Warrior and Predator when a common payload could be achieved—currently the basic sensors are 80 percent common and manufactured by the same contractor. However, according to Army officials, the Air Force sensor is more expensive and has capabilities, such as high-definition video, for which the Army has no requirements. Therefore, the Army does not believe a fully common solution is warranted. [27]

It should be noted that the number of systems acquired does not correspond to the number of unique platforms. By installing different sensors, a mostly-common airframe can be made to serve the requirements of multiple services. The General Atomics I-GNAT developed into the Air Force Predator and Reaper, which served as the basis for the Army Gray Eagle and DHS's Predator optimized for marine environments; Northrop Grumman's Air Force Global Hawk became, with different equipment, the Navy's Broad Area Maritime Surveillance (BAMS) system.

[27] U.S. Government Accountability Office, *Defense Acquisitions: Opportunities Exist to Achieve Greater Commonality and Efficiencies among Unmanned Aircraft Systems*, 09-520, July 2009, page 4.

2979 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

This is not to say that the resulting systems are the same. Due to different requirements and payloads, a BAMS, for example, costs almost twice as much as a Global Hawk. This commonality may, however, provide an argument for those who advocate greater jointness in UAS development.

Does the Department of Defense Have an Integrated UAS Development Policy?

In September, 2007, the Secretary of Defense ordered creation of a UAS Task Force within the office of the Under Secretary of Defense for Acquisition, Technology and Logistics.[28] [29] The Task Force's charter gives it the responsibility to coordinate UAS requirements among the services, "promot[e] the development and fielding of interoperable systems and networks," and to "[s]hape DoD UAS acquisition programs to prioritize joint solutions." The charter does not give the Task Force the authority to terminate redundant programs nor compel their consolidation. Thus, development of UAS in DOD can be said to be federated, but not integrated.

DOD also issues a biannual roadmap indicating what technologies and capabilities it expects to see in future systems, and attempting to project the requirements for broad UAS capabilities 25 years into the future.[30] Development of UAS is still carried out by individual military services.

UAS programs range from the combat tested—Pioneer, Hunter, Predator and Global Hawk—to the not yet tested—the Air Force and Navy's Unmanned Combat Air Vehicles. Sizes and ranges of UAVs also vary greatly: the 8-inch-long Wasp Micro UAV has a combat radius of 5 nautical miles, while the 44-foot-long Global Hawk (the size of a medium sized corporate jet) has a combat radius of 5,400 nm.[31]

Table 1 outlines the total UAV inventory.[32] When compared to the inventory of February 2003, which only included five major platforms and an inventory of 163 unmanned aircraft, the acceleration and expansion becomes clear. The 7454 UAVs include many 2nd generation derivatives, such as Predator B and BAMS, and some non-traditional vehicles, such as gMAV and T-Hawk.

[28] Under Secretary of Defense (Acquisition, Technology and Logistics), *Department of Defense Report to Congress on Addressing Challenges for Unmanned Aircraft Systems*, September 2010.

[29] Creation of the UAS Task Force was a compromise outcome. DOD had sought to designate a single executive agent to oversee UAS development across the Department. The Air Force actively sought the role, but other services did not support their bid.

[30] See, for example, Department of Defense, *FY2009–2034 Unmanned Systems Integrated Roadmap* (2009).

[31] For a more comprehensive treatment of these UAV programs, see the "Current DOD UAV Programs" section below.

[32] Note that these inventories do not include small UAVs, micro UAVs or lighter-than-air platforms.

2981 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The increase in DOD's UAV inventory appears largely due to the rising demand for UAVs to branch out from the typical intelligence, surveillance and reconnaissance (ISR) applications and conduct a wider variety of missions. Predator B and Reaper are equipped with a strike capability, and many Predator As have been modified to carry weapons. Additionally, mine detection, border patrol, medical resupply, and force perimeter protection are increasingly considered as roles for UAS.

In order to understand fully the pace and scope of UAS acquisition, a comparison between manned aircraft inventories and unmanned inventories may prove to be a useful tool. **Figure 2** shows the ratio of manned to unmanned aircraft. Due to the recent acceleration in UAS production and drawdowns in manned aircraft, manned aircraft have gone from 95% of all DOD aircraft in 2005 to 69% today. Previously described as complements to, or augmentation of, manned aircraft, user demand and budgetary push have increasingly promoted UAS into a principal role.

Figure 1. Manned Aircraft Inventory vs. UAS Inventory

Source: The Military Balance 2010; Weatherington brief.

A significant Congressional boost to UAS acquisition came in the conference report for the National Defense Authorization Act for Fiscal Year 2001, which expressed Congress's desire that "within ten years, one-third of U.S. military operational deep strike aircraft will be unmanned."[33] This goal was seen at the time as very challenging, because DOD had no unmanned deep strike aircraft.

Subsequently, the Fiscal 2007 Defense Authorization Act required the Secretary of Defense to "develop a policy, to be applicable throughout the Department of Defense, on research, development, test and evaluation, procurement, and operation of unmanned systems." The policy was required to include, among other elements, "A preference for unmanned systems in acquisition programs for new systems, including a requirement under any such program for the

[33] H.Rept. 106-945, U.S. Congress, Enactment of Provisions of H.R. 5408, the Floyd D. Spence National Defense Authorization Act For Fiscal Year 2001, Conference report to accompany H.R. 4205, 106th Cong., 2nd sess., October 6, 2000, section 220.

2982 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

development of a manned system for a certification that an unmanned system is incapable of meeting program requirements."[34] Thus, Congress changed the default assumption of new systems; instead of seeking unmanned systems to accomplish the same tasks as manned equivalents, unmanned systems would be developed to accomplish military tasks unless there was some need that the systems be manned.

UAS Management Issues

In addition to establishing acquisition pace, and scope of application, one significant Congressional task may be to determine whether DOD's administrative processes and lines of authority within the acquisition process are effective for UAS development and acquisition. The management of DOD's development and acquisition programs received heightened attention in recent Congresses. Given that UAS are acquired by all four of the military services and the U.S. Special Operations Command, and that UAS acquisition is accelerating, (for a growing list of applications), it appears that great potential exists for duplication of effort. This leads many to call for centralization of UAS acquisition authority, to ensure unity of effort and inhibit wasteful duplication. On the other hand, if UAS efforts are too centralized, some fear that competition and innovation may be repressed.

Cost Management Issues

Once viewed as a cheap alternative to manned aircraft, or even a "poor man's air force," some UAS are beginning to rival manned aircraft in cost. According to DOD's most recent estimate, the Global Hawk program will cost $13.9 billion to purchase 54 aircraft; a program acquisition unit cost of $211 million per UAV.[35] The program has twice triggered Nunn-McCurdy breaches, which require DOD to notify Congress when cost growth on a major acquisition program reaches 15%.[36] In 2005, development cost overruns led to an average unit cost growth of 18% per airframe and prompted appropriators to voice their concern (H.R. 2863, H.Rept. 109-119, p. 174). In April, 2011, a reduction in the number of Global Hawk Block 40 aircraft requested in the FY2012 budget from 22 to 11 caused overall Global Hawk unit prices to increase by 11%, again triggering Nunn-McCurdy.

> [T]he RQ-4 Global Hawk surveillance drone, by Northrop Grumman [NOC] has been criticized by the Air Force for higher than expected cost growth. [Under Secretary of Defense Ashton] Carter said that program is "on a path to being unaffordable" and will be studied in detail to determine what is causing the suspected inefficiencies.[37]

Much UAS cost growth appears to spring from factors that have also affected manned aircraft programs, such as "requirements creep" and inconsistent management practices. Global Hawk

[34] P.L. 109-364, *John Warner National Defense Authorization Act for Fiscal Year 2007*, section 941.

[35] OSD (AT&L), *Selected Acquisition Report (SAR): RQ-4A/B UAS Global Hawk*, December 31, 2010. Costs are expressed in constant 2002 dollars.

[36] The Nunn-McCurdy provision requires DOD to notify Congress when cost growth on a major acquisition program reaches 15%. If the cost growth hits 25%, Nunn-McCurdy requires DOD to justify continuing the program based on three main criteria: its importance to U.S. national security; the lack of a viable alternative; and evidence that the problems that led to the cost growth are under control. For more information, see CRS Report R41293, *The Nunn-McCurdy Act: Background, Analysis, and Issues for Congress* , by Moshe Schwartz.

[37] Marina Malenic, "Pentagon Unveils Belt-Tightening Plan For Acquisition Programs," *Defense Daily*, June 29, 2010.

2983 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

costs, for example, have been driven up by adding multiple sensors, which themselves increase cost, but also require larger wings and more powerful engines to carry the increased weight, which also increases cost. Although originally intended to carry one primary sensor at a time, DOD changed the requirement so that Global Hawk is to carry two or more primary sensors—which has increased the UAS's price.[38]

Global Hawk is not the only example of requirements creep. Originally considered a relatively modest UAS, the Joint Unmanned Combat Air System (J-UCAS) evolved into a large, long range aircraft with a heavy payload, which increased cost. J-UCAS was canceled in 2006.

Organizational Management issues

The frequent change and realignment of DOD's organizations with a role in UAS development illustrates the difficulties of establishing a comprehensive UAS management system. Over the years, management of UAS programs has gone full circle from the military services, to a Navy-run Joint Program Office (JPO), to the Defense Airborne Reconnaissance Office (DARO) and then back to the services, under the auspices of OSD. The JPO was established in 1988, but met criticism in Congress.

The JPO was replaced by the Defense Airborne Reconnaissance Office (DARO), created in 1993 to more effectively manage DOD's disparate airborne reconnaissance programs, including UAS. DARO was disbanded in 1998, amid criticism of problems, redesigns, and accidents with the family of systems that it was formed to develop.[39] It is unclear whether this criticism was completely legitimate, or whether it was generated by advocates of manned aviation, who sought to protect these established programs.

Since DARO's demise, no single organization has managed DOD UAS efforts. General oversight authority resides within the Office of the Assistant Secretary of Defense for Command, Control, Communications and Intelligence (OASD(C3I)), while the military services manage program development and acquisition.

In an effort to increase joint coordination of UAS programs operated by the services, OSD established the Joint UAV Planning Task Force in 2001. The task force, which falls under the authority of the Pentagon's acquisition chief (Under Secretary of Defense for Acquisition, Technology and Logistics), works to help standardize payload development, establish uniform interfaces, and promote a common vision for future UAS-related efforts. Subsequently, the Joint UAV Planning Task Force has been promoted to the top rung on the UAS management ladder.

> In lieu of creating an executive agent for UAS, the Deputy Secretary of Defense (DepSecDef) directed the formation of a UAS Task Force (TF). The TF was directed to identify to the Deputy Advisory Working Group (DAWG) and, where appropriate, assign lead organizations for issues related to the acquisition and management of UAS including interoperability, civil airspace integration, frequency spectrum and bandwidth utilization, ground stations, and airframe payload and sensor management.[40]

2984 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In order to help a common UAS vision become a reality, the task force, through the OSD, published three UAS Roadmaps in April 2001, December 2002, and August 2005. A more recent UAS roadmap was published in April 2009 as part of a DOD integrated roadmap that also included unmanned systems for ground and sea warfare.

In March 2005 testimony to the House Armed Services Subcommittee on Tactical Air and Land Forces, the GAO criticized DOD for the lack of an " ... oversight body to guide UAV development efforts and related investment decisions," which ultimately does not allow DOD " ... to make sound program decisions or establish funding priorities."[41] From the testimony, it would appear that the GAO envisioned a central authority or body to satisfy this role.

In what appeared to be a move toward further management restructuring, reports in 2005 indicated that OSD was considering appointing one of the services as the executive agent and coordinator for UAS programs, a role the Air Force actively pursued.[42] However, later that year the JROC announced that DOD had abandoned the notion of an executive agent in favor of two smaller organizations focusing on interoperability.[43] The first, entitled the Joint UAV Overarching Integrated Product Team (OIPT), provides a forum for identification and problem solving of major interoperability and standardization issues between the services.[44] A complementary Joint UAV Center of Excellence coordinates with the OIPT to improve interoperability and enhance UAS applications through the examination of sensor technologies, UAS intelligence collection assets, system technologies, training and tactics.[45]

That command arrangement was revised in 2007, when the Deputy Secretary of Defense directed the formation of a UAS Task Force.[46] The task force was directed to, "where appropriate, assign lead organizations for issues related to the acquisition and management of UAS including interoperability, civil airspace integration, frequency spectrum and bandwidth utilization, ground stations, and airframe payload and sensor management."[47] That arrangement remains in place today.

UAS and Investment Priorities

All four military services, the U.S. Special Operations Command (SOCOM), and the U.S. Coast Guard are developing and fielding UAS. Developing a coordinated, DOD-wide UAS investment strategy appears key to ensuring duplication is avoided, and scarce resources are maximized. As

part of its defense oversight role, Congress is positioned to arbitrate between competing UAS investments, or impact DOD's overarching investment plan. Several relevant questions seem apparent: How is UAS cost quantified? What is the most effective balance in spending between UAS and manned aircraft? How should DOD, Congress and the UAS manufacturers balance cost with capability? Finally, what areas of investment are the most important to maximize UAS capabilities?

When compared to other aircraft, the cost of an individual remotely piloted vehicle can be misleading. UAVs operate as part of a system, which generally consists of a ground control station, a ground crew including remote pilots and sensor operators, communication links and often multiple air vehicles. Unlike a manned aircraft such as an F-16, these supporting elements are a requisite for the vehicle's flight.[48] Consequently, analysts comparing UAV costs to manned aircraft may need to consider the cost of the supporting elements and operational infrastructure that make up the complete unmanned aviation system.

Monitoring or evaluating UAS costs can also be complicated by budgeting conventions. While UAVs can be found in the "Aircraft Procurement, Air Force" account in that service's budget request documentation, the Army includes its UAS funding requests in "Other Procurement, Army." This account contains a broad range of dissimilar items. Also, because most UAS conduct Intelligence, Surveillance and Reconnaissance missions, some portion of their costs are covered in the Intelligence budget rather than the DOD budget, which complicates building a complete picture of cost.

Once an adequate and uniform cost comparison mechanism or definition has been established, the next step for Congress may be to identify an appropriate balance in spending between UAS and manned aircraft. If the upward trend in UAS funding continues through 2013, as shown in **Figure 3**, DOD is projected to have spent upwards of $26 billion on procurement, RDT&E, operations and maintenance for UAS from 2001-2013. This number far exceeds the $3.9 billion spent on UAS from 1988-2000.

Table 2. FY2011-FY2013 President's Budget for UAS

	FY11	FY12	FY13
RDT&E	$1076.4	$894.0	$719.5
PROC	$1704.7	$1734.3	$1576.2
O&M	$249.0	$274.9	$320.2
TOTAL	$3,030.1	$2,903.2	$2,615.9

Source: DOD FY2009–2034 Unmanned Systems Integrated Roadmap, April, 2009, page 4.

[48] Manned aircraft like the F-16 do require radar operators and air traffic controllers in order to maximize their performance, yet these are not required for flight. An F-16 needs a pilot in the cockpit and little else. UAVs, with the exception of the few autonomous flight models, require constant intervention and control from a ground crew. The probability that an F-16 could sustain flight without communication from its ground crew is relatively high, whereas the lack of communication between the ground operators and the UAV yields a low probability of sustained flight.

Figure 3 demonstrates the total funding for UAS as a percentage of the total military aviation funding. As the pie chart shows, despite the recent acquisition of many UAS, such systems represent only 8% of all military aviation procurement funding.

Figure 3. Manned vs. Unmanned Aircraft Procurement Budget (FY2011)

Source: DOD UAS Roadmap 2009-2030; FY2011 DOD justification books for procurement of manned aircraft. Does not include small UAVs, micro-UAVs or lighter-than-air platforms.

Cost savings have long been touted by UAS advocates as one of the advantages offered by unmanned aircraft over manned aircraft. However, critics point out that the acquisition cost savings are often negligible if one considers that money saved by not having a pilot in the cockpit must be applied to the "ground cockpit" of the UAS aircrew operating the UAV from the ground control station. Another cost question concerns personnel. Do UAS "pilots" cost less to train and

2987 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

keep proficient than pilots of manned aircraft?[49] So although the air vehicle might be cheaper than a manned aircraft, the UAV system as a whole is not always less expensive.[50] Additionally, UAS have a higher attrition rate and lower reliability rate than manned aircraft, which means that the operation and maintenance costs can be higher. On the other hand, UAS ground control stations are capable of simultaneously flying multiple UAVs, somewhat restoring the advantage in cost to the unmanned system. Congress has noted that, "while the acquisition per unit cost may be relatively small, in the aggregate, the acquisition cost rivals the investment in other larger weapon systems."[51]

At what threshold does an "expendable" UAV cost too much to lose? Sensors have consistently increased the cost of the air vehicle, according to Former Air Force Secretary James Roche.[52] The inexpensive design of small UAV air vehicles like the Desert Hawk and Dragon Eye are dwarfed by the cost of the lightweight electro-optical/infrared cameras that make up their payloads. On the other end of the size spectrum, the RQ-4B second generation Global Hawk's sensor payload represents approximately 54% of the vehicle's flyaway cost, which does not include the cost of the increased wingspan that shoulders the extra 1000 pounds of sensor suites.[53] These costs are increasing due to the basic law of supply and demand. Growing demand, matched with a lack of commercial sensor equivalents, means that UAS sensor producers face little competition, which would help keep costs down.

Growing sensor costs have prompted some observers to recommend equipping UAVs with self-protection devices, suggesting those UAVs are no longer considered expendable. Consequently, two schools of thought exist for employing UAVs in ways that could help balance cost with capability. One is to field many smaller, less expensive and less capable UAVs controlled through a highly interconnected communications network.[54] One example of this investment approach was included in the Army's developmental Future Combat System, which intended to link several relatively inexpensive UAVs like the Raven, the Shadow and the Fire Scout with 18 other weapons platforms. None of these UAVs could individually shoulder all of the air duties required by the system, yet the robust communications network was expected to distribute the mission duties to allow each platform to provide its specialized task.[55]

A second approach advocates fielding fewer, more expensive and more capable UAVs that are less networked with other systems, such as the autonomous Global Hawk. The Global Hawk serves as a high altitude, "all-in-one" surveillance platform capable of staying aloft for days at a time, yet does not operate in concert with any of its fellow UAV peers. Since 2003, programs at both ends of this spectrum have experienced delays and a reduction in funding. The Army's

[49] For more on personnel issues, see "Recruitment and Retention" section below.

[50] As an example, a Predator air vehicle costs $4.5 million, while the Predator system, including four air vehicles and control equipment, costs over $20 million.

2988 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Future Combat System has experienced delays due to significant management and technology issues. Similarly, the highly capable Global Hawk has risen in cost and been the target of funding cuts.[56]

Finally, what areas of investment will yield the maximum effectiveness out of these UAS? Four specific issues stand out as the most pressing: interoperability, reliability, force multiplication/autonomy, and engine systems.

Interoperability

UAS development has been marked by the slow advancement of interoperability. The future plans for UAS use within the framework of larger battlefield operations and more interconnected and potentially joint-service combat systems require UAS to communicate seamlessly between each other and numerous different ground components, and to also be compatible with diverse ground control systems. The lack of interconnectivity at these levels has often complicated missions to the point of reducing their effectiveness, as Dyke Weatherington, head of DOD's UAS planning taskforce, noted; "There have been cases where a service's UAV, if it could have gotten data to another service, another component, it may have provided better situational awareness on a specific threat in a specific area that might have resulted in different measures being taken."[57]

Advancing the interoperability of UAS has been a critical part of the OSD's investment plans. The Department of Defense has pushed forward with the establishment of communication between similar UAS to help facilitate interoperability among four system elements:[58]

- First, DOD hopes to integrate an adequate interface for situational awareness, which will relay the objective, position, payload composition, service operator and mission tasking procedure to other unmanned aircraft and potentially to ground elements.
- Second, a payload interface will allow the coherent transfer of surveillance data.
- Third, the weapons interface will constitute a separate transfer medium by which operators can coordinate these platform's offensive capabilities.
- Finally, the air vehicle control interface will enable navigation and positioning from the ground with respect to other aircraft.

Although the framework for these categories of interoperability has been established, the technology has been slow to catch up. The House of Representatives version of the FY2006 Defense Authorization Act (H.R. 1815, H.Rept. 109-89) took a major step to encourage inter-platform communication. The members of the House Armed Services Committee included a clause that called for the requirement of all tactical unmanned aerial vehicles throughout the services to be equipped with the Tactical Common Data Link, which has become the services' standardized communication tool for providing "critical wideband data link required for real-time situational awareness, as well as real time sensor and targeting data to tactical commanders."[59] If

2989 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

UAS are to achieve the level of interoperability envisioned by the OSD, the services and industry will likely need to keep focused on achieving the Common Data Link communications system goal and invest appropriately to facilitate an expedited and efficient development process.

The finite bandwidth that currently exists for all military aircraft, and the resulting competition for existing bandwidth, may render the expansion of UAS applications infeasible and leave many platforms grounded. Ultimately, the requirement for bandwidth grows with every war the U.S. fights.[60] The increased use of UAS in Iraq and Afghanistan indicates that remotely piloted platforms' mass consumption of bandwidth will require a more robust information transfer system in the coming years.

One approach to alleviating the bandwidth concern was the Transformational Satellite Communications (TSAT) project. DOD intended to use that laser and satellite communications system to provide U.S. armed forces with an unlimited and uninhibited ability to send and receive messages and critical information around the world without data traffic jams.[61] However, the TSAT project was canceled in 2009. As another interim option, DOD has testified that a more autonomous UAV would require less bandwidth, since more data are processed on board and less data are being moved.[62] However, it is unclear that autonomy will actually decrease bandwidth requirements since the transmission of data from the UAV's sensors drives the demand for bandwidth. As an example, a single Global Hawk, already an autonomous UAV, "requires 500Mbps bandwidth—which equates to 500 percent of the total bandwidth of the entire U.S. military used during the 1991 Gulf War."[63]

Another approach to alleviating the bandwidth problem is allowing UAVs to be operated from a manned stand-off aircraft such as a command and control aircraft with line of sight to the UAV. Stationing the mission control element of the UAV system in another aircraft instead of on the ground would reduce the reliance on satellites for beyond-line-of-sight communication, simplifying command and control. Experimentation is currently ongoing in this area, with the first step being controlling the UAV's sensor payload from an airborne platform.

Reliability/Safety

A 2010 media study reported that "Thirty-eight Predator and Reaper drones have crashed during combat missions in Afghanistan and Iraq, and nine more during training on bases in the U.S.—

with each crash costing between $3.7 million and $5 million. Altogether, the Air Force says there have been 79 drone accidents costing at least $1 million each."[64]

In 2004 the Defense Science Board indicated that relatively high UAV mishap rates might impede the widespread fielding of UAVs.[65] Although most UAV accidents have been attributed to human error,[66] investment in reliability upgrades appears to be another high priority for UAS. The 2005 UAS Roadmap indicated that UAV mishap rates appeared to be much higher than the mishap rates of many manned aircraft. **Table 3** shows the number of Class A Mishap per 100,000 hours of major UAVs and comparable manned aircraft as of 2005.[67]

Table 3. Selected Mishap Rates, 2005

(per 100,000 hrs)

Vehicle Type	Class A Mishaps
UAV	
Predator	20
Hunter	47
Global Hawk	88
Pioneer	281
Shadow	191
Manned	
U-2	6.8
F-16	4.1

Source: DOD's UAS Roadmap 2005-2030, p. 75.

However, "(a)ccident rates per 100,000 hours dropped to 7.5 for the Predator and 16.4 for the Reaper last year (2009), according to the Air Force. The Predator rate is comparable to that of the F-16 fighter at the same stage, Air Force officers say, and just under the 8.2 rate for small, single-engine private airplanes flown in the U.S."[68]

[64] David Zucchino, "War zone drone crashes add up," *Los Angeles Times*, July 6, 2010.

[65] Defense Science Board. "Defense Science Board Study on Unmanned Aerial Vehicles and Uninhabited Combat Aerial Vehicles." Office of the Undersecretary of Defense for Acquisitions, Technology, and Logistics. February 2004, p.vii-viii.

[66] A 2005 study cited human operational or maintenance mistakes as causing 68% of UAV accidents. William T. Thompson, Major Anthony P. Tvaryanas, and Stefan H. Constable, *U.S. Military Unmanned Aerial Vehicle Mishaps: Assessment of the Role of Human Factors Using Human Factors Analysis and Classification System (HFACS)*, U.S. Air Force, 311th Human Systems Wing, HSW-PE-BR-TR-2005-0001, Brooks City-Base, TX, March 2005.

[67] Note that Class A mishaps, according to the Army Safety Center, are considered to be damage costs of $1,000,000 or more and/or destruction of aircraft, missile or spacecraft and/or fatality or permanent total disability. Similar definitions for the Air Force, Navy and Marine Corps can be found at their respective safety center websites. Also note the performance capabilities of the manned versus unmanned vary greatly and may have an impact on the mishap rate. Finally, note that the definition of a Class A mishap is not indexed for inflation, so the actual damage need to reach $1 million in cost effectively declines each year.

[68] David Zucchino, "War zone drone crashes add up," *Los Angeles Times*, July 6, 2010.

2991 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In its 2004 study, the Defense Science Board (DSB) notes that manned aircraft over the past five decades have moved from a relatively high mishap rate to relatively low rates through advancements in system design, weather durability improvements and reliability upgrades.[69] It should be pointed out, however, that the UAS, with the exception of Predator, have total flight times that are significantly less the than the 100,000 hours used to calculate the mishap rate. Most aircraft tend to have a much higher mishap rate in their first 50,000 hours of flight than their second 50,000 hours of flight. Further, some of the UAS in **Table 3** have flown numerous missions while still under development. Predator and Global Hawk, for instance, entered combat well prior to their planned initial operational capability (2005 for Predator, and 2011 for Global Hawk.) It may be unfair to compare the mishap rates of developmental UAS with manned aircraft that have completed development and been modernized and refined over decades of use.

The DSB report also suggests that nominal upgrades and investment—arguing even that many UAS will need little change—could produce substantial reductions in the UAV mishap rates. The 2005 UAS Roadmap proposes investments into emerging technologies, such as self-repairing "smart" flight control systems, auto take-off and recovery instruments, and heavy fuel engines, to enhance reliability.[70] Also the incorporation of advanced materials—such as high temperature components, light-weight structures, shape memory alloys and cold weather tolerance designs that include significant de-icing properties—will also be expected to improve the survivability of UAS in adverse environments.[71]

Force Multiplication/Autonomy

One of the most attractive and innovative technological priorities for UAS is to enable one ground operator to pilot several UAVs at once. Currently most UAS require at least two ground operators; one to pilot the vehicle and another to control the sensors. The end goal for UAS manufactures and users is to reduce the 2:1 operator-vehicle ratio and eventually elevate the autonomy and interoperability of UAS to the point where two or more vehicles can be controlled by one operator. If this technological feat is achieved, the advantage of UAS as a force-multiplier on the battlefield could provide a dramatic change in combat capability.

The process of achieving this goal may require significant time and investments. As the 2005 UAS Roadmap notes, "Getting groups of UA to team (or swarm) in order to accomplish an objective will require significant investment in control technologies" with specific reference to distributed control technologies.[72] Considering the two operator system currently in place for most UAS, the logical approach to reaching this technological advancement is to first invest in the autonomous flight capabilities of the UAVs, so as to reduce the workload for the complete UAS. The Global Hawk and the Scan Eagle possess significant automated flight capabilities, but their degree of actual flight autonomy can be debated due to the UAV's need for continuous operator intervention in poor weather conditions. The OSD quantifies the degree of UAV autonomy on a scale of one to ten; **Table 4** shows the OSD's Autonomous Capability Levels for UAVs.

In order for UAVs to achieve maximum use when being controlled by a single pilot, the UAV ACL must achieve a level of at least eight. Currently, the Global Hawk, which is considered by many the most autonomous UAV currently in service, maintains an ACL of approximately 2.5. FAA and the UAS industry are working with the Department of Defense in order to facilitate the universal development of "see and avoid" technology that would allow a UAV to operate autonomously and avoid approaching aircraft, potentially increasing the standard ACL for UAS to four. Additionally, inter-UAS communication and the coordination associated with interoperability must match the autonomous flight abilities. Full automation of sensor capabilities would enable the lone operator to control a network of intelligence collecting drones.

The first steps towards the "one-operator-per-several-UAVs" advancement are already underway.In 2005, the Air Force evaluated a Predator upgrade that allowed one operator to control the flight plan of four Predator UAVs during an exercise in which one UAV engaged a target and the other three hovered nearby on standby status. [73] The next step is to consolidate the tasks of the four mission payload operators, each manning the sensors or weapons system on the four Predators, into one or fewer operators.

Engine Systems

Another technology under development is fuel cell-generated electric power. Supporters of fuel cells note that these devices could double the efficiency of mid-sized UAS and could reduce the aircrafts' acoustic and thermal signatures, effectively making them more difficult to detect and target.[74] Air Combat Command is sponsoring the project with the goal to use the fuel cells in many of its smaller UAS, and the Air Force Research Laboratory flight tested a fuel cell-powered

Puma UAV in 2007. "With a power system using a chemical hydride fuel, the UAV demonstrated flight endurance of more than 7 hr., versus 2.5 hr. for the standard Puma."[75] [76]

Figure 4. UAS Technology Futures

Source: DOD FY2009–2034 Unmanned Systems Integrated Roadmap, April, 2009, Page 30.

Note: SA is "situational awareness," although in this context "Sense and Avoid" capability is also an appropriate fit for the acronym.

Some key technologies that will enable future UAS include:

> lightweight, long endurance battery and/or alternative power technology, effective bandwidth management/data compression tools, stealth capability and collaborative or teaming technologies that will allow UAS to operate in concert with each other and with manned aircraft. A critical enabler allowing UAS access to U.S. National and ICAO airspace will be a robust on-board sense and avoid technology. The ability of UAS to operate in airspace shared with civil manned aircraft will be critical for future peacetime training and operations. There is also a need for open architecture systems that will allow competition among many different commercial UAS and ground control systems allowing DoD to "mix and match" the best of all possible systems on the market. Technology enablers in propulsion systems coupled with greater energy efficiency of payloads are required to extend loiter time and expand the missions of UAS to include Electronic Attack and directed energy.[77]

Duplication of Capability

Congress may ask if the production of different UAS with relatively similar performance capabilities constitutes unnecessary duplication. Critics of expanded UAS roles often argue that the production of similar platforms is unnecessary, considering that a consolidated inventory—

[75] David Eshel, "Mini-UAVs rack up big gains," *Defense Technology International*, May 15, 2008.

[76] Fuel cell technology has already been tested on other types of aircraft:."German Aerospace Centre has converted an Antares 20E, the DLR-H2, to fly with a fuel cell. Boeing has also flown a Dimona motor glider with an electric motor powered by a fuel cell. And United Technologies, which makes Sikorsky helicopters, has flown a large model electric-helicopter powered by a hydrogen fuel cell." "Electric planes: High voltage," *The Economist*, June 10, 2010.

hypothetically consisting of only the RQ-4B Global Hawk, the RQ/MQ-1 Predator and the RQ-7 Shadow—could perform and fulfill the same duties as the expanded inventory.

According to GAO, for example,

> Although several unmanned aircraft programs have achieved airframe commonality, service-driven acquisition processes and ineffective collaboration are key factors that have inhibited commonality among subsystems, payloads, and ground control stations. For example, the Army chose to develop a new sensor payload for its Sky Warrior,[78] despite the fact that the sensor currently used on the Air Force's Predator is comparable and manufactured by the same contractor. To support their respective requirements, the services also make resource allocation decisions independently. DOD officials have not quantified the potential costs or benefits of pursuing various alternatives, including common systems. To maximize acquisition resources and meet increased demand, Congress and DOD have increasingly pushed for more commonality among unmanned aircraft systems. [79]

Table 5 shows a comparison of the performance specifications of UAS with electro-optical and infra-red sensors. The chart indicates that a majority of such UAS feature an endurance of 5 to 24 hours, an altitude of 10,000 - 25,000 ft, max speeds between 105 and 125 knots and radiuses of 100 to 150 nm.

Table 5. ISR UAS with E-O/IR Sensors

	Vehicle Endurance (hrs) Max	Altitude (ft) Max	Speed (kt)	Range (nm)	Additional Sensor	User
Eagle Eye	5.5	20000	210	110	MMR	Coast Guard

carry approximately four times the payload of the Reaper (10,750 lbs vs. 2,500 lbs).[81] Further, the F-16 is a versatile combat aircraft that can be used to perform many missions that the Reaper cannot. This may suggest that using manned aircraft for air-to-ground combat may generally prove more cost effective than using UAS, and that the UAS's unique combat capabilities may be most valued in niche circumstances, such as when manned aircraft would be in extreme danger.

Other Potential Missions

Other missions for which UAS appear useful, or are being considered in the near-term, include electronic attack (also called stand-off jamming, or escort jamming), and psychological operations, such as dropping leaflets. UAS such as the Army's Shadow have been evaluated for their capability to deliver critical medical supplies needed on the battlefield.

While UAS use in foreign theaters is well established, one of the most commonly discussed new mission areas for UAS is homeland defense and homeland security. The Coast Guard and U.S. Border Patrol already employ UAS such as the Eagle Eye and Predator to watch coastal waters, patrol the nation's borders, and protect major oil and gas pipelines.

It appears that interest is growing in using UAS for a variety of domestic, and often non-defense roles. Long-duration law enforcement surveillance, a task performed by manned aircraft during the October 2002 sniper incident near Washington, D.C. is one example. The U.S. Department of Transportation has studied possible security roles for UAS, such as following trucks with hazardous cargo, while the Energy Department has been developing high-altitude instruments to measure radiation in the atmosphere.[82] UAS might also be used in sparsely populated areas of the western United States to search for forest fires. Following the wide-spread destruction of Hurricane Katrina, some suggest that a UAS like Global Hawk could play roles in "consequence management" and relief efforts.[83] Also, UAS advocates note that countries like South Korea and Japan have used UAS for decades for crop dusting and other agricultural purposes.[84]

> Historically, UAS were predominately operated by DoD in support of combat operations in military controlled airspace; however, UAS support to civil authorities (JTF Katrina in 2005, U.S. Border surveillance, and fire suppression) continues to expand. This expansion, coupled with the requirement to train and operate DoD and [other government agency] assets,

> highlights the need for routine access to the [national airspace system] outside of restricted and warning areas, over land and water. [85]

Heavier-than-air UAS may not always be the preferred platforms for these new roles and applications. Other options could include manned aircraft, blimps, and space satellites.[86] Each platform offers both advantages and disadvantages. Manned aircraft provide a flexible platform, but risk a pilot's life. Some of the country's largest defense contractors are competing to develop unmanned blimps that may be capable of floating months at a time at an altitude of 70,000 feet and carrying 4,000 pounds of payload. OSD's UAS Roadmap includes a section on lighter-than-air blimps and tethered "aerostat" platforms, which OSD indicates to be important for a variety of roles, including psychological operations, spotting incoming enemy missiles and border monitoring. Furthermore, these platforms could provide services equivalent to many border surveillance UAS, but their decreased dependency on fuel could reduce operations costs. One drawback to these lighter-than-air platforms is their lack of maneuverability and speed relative to UAVs like the Global Hawk; their long persistence once on station may be somewhat offset by the time required for them to relocate in response to new taskings. Nonetheless, many major UAS manufacturers are preparing—and, in some cases, testing—lighter-than-air systems that could carry out a variety of missions for homeland security.[87]

Space satellites offer many benefits; they are thought to be relatively invulnerable to attack, and field many advanced capabilities. However, tasking the satellites can be cumbersome, especially with competing national priorities. The limited number of systems can only serve so many customers at one time. Additionally, some satellites lack the loitering capability of UAS, only passing over the same spot on Earth about once every three days. Due to the high costs of space launches, UAVs like Global Hawk are being considered for communication relays as substitutes for low-orbiting satellite constellations.[88]

The Issue of Airspace

Not all of these new UAS applications are uncontroversial or easily implemented. UAS advocates state that in order for UAS to take an active role in homeland security, law enforcement, aerial surveying, crop dusting, and other proposed civilian uses, Federal Aviation Administration (FAA) regulations and UAS flight requirements must approach a common ground. According to FAA spokesman William Shumann, the primary challenge in finding this common ground is "to develop vehicles that meet FAA safety requirements if they want to fly in crowded airspace." [89] The August 2003 announcement that the FAA had granted the Air Force a certificate of authorization for national airspace operation signified the first steps in the reconciliation of these discrepancies.[90] Upgrading UAS collision avoidance capabilities, often referred to as "sense and avoid" technology, appears to be a critical part in the next step of reaching the UAS-airspace

2997 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

common ground. The FAA's Unmanned Aircraft Systems Working Group is working with the Department of Defense to facilitate safe UAS operations and the adequacy of flight requirements.[91]

The schedule for integrating UAS into the national airspace remains contentious. Industry has expressed frustration at not being able to test new UAS from their own test facilities due to airspace restrictions. Also:

> DOD has pioneered UAS applications for wartime use and, in 2007, was the major user of UAS, primarily for ongoing conflicts in Iraq and Afghanistan. While many of DOD's UAS operations currently take place outside the United States, DOD needs access to the national airspace system for UAS to, among other things, transit from their home bases for training in restricted military airspace or for transit to overseas deployment locations.[92]

In November 2009, Secretary of the Air Force Michael Donley and FAA Administrator Randy Babbitt co-moderated an industry forum on UAS in the national airspace system. At that event, Administrator Babbitt said:

> In order for us to get to the place where the UAS can become a viable, accepted part of the national airspace system, we have to make sure that sense-and-avoid is more than a given—it must be a guarantee.
>
> Without a pilot who can look and scan to the left and the right—just the way you and I do when we're backing out of a parking space—there's a perceived level of risk that the American public isn't ready for.[93]

The issue of when and how UAS will be allowed to operate in U.S. airspace continues to evolve, and continues to be of interest to Congress. The House passed a proposed FAA reauthorization bill in 2011 which "includes a provision requiring FAA to develop a comprehensive plan within nine months of enactment to safely integrate commercial unmanned aircraft systems (UASs) in the national airspace system. The bill further specifies that this integration is to be completed as soon as possible, but not later than September 30, 2012, and authorizes such sums as may be necessary to carry out the implementation plan."[94] A companion Senate bill "includes a provision requiring FAA to develop a plan for accelerating the integration of UASs into the National Airspace System within one year of enactment." More detailed information on this issue can be found in CRS Report R41798, *Federal Aviation Administration (FAA) Reauthorization: An Overview of Legislative Action in the 112th Congress*.

Recruitment and Retention

The defining characteristic of UAS is that they are "unmanned" or "unpiloted." However, this may be a misnomer.

[91] "UAV Sense-And-Avoid Technologies Not Just A Military Concern." *Defense Daily*. August 2, 2005.

2998 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> "There's nothing unmanned about them," [former Air Force Lt Gen David] Deptula said. It can take as many as 170 persons to launch, fly, and maintain such an aircraft as well as to process and disseminate its ISR products. [95]

Recruitment and retention is a perennial congressional issue that may be receiving increased attention due to the operational stresses associated with the ongoing efforts to counter terrorism. What impact might wide spread deployment of UAS have on military personnel? If UAS are introduced into the force in large numbers, might personnel issues arise?

It has not always been easy for the aviation culture to adapt to flying aircraft from the ground. The Air Force has realized the retention implications of requiring rated pilots to fly their UAS,[96] and has offered enticements such as plum assignments after flying the UAS, and allowing pilots to keep up their manned flying hours during their UAS tour of duty.

Historically, many believed that as more UAS were fielded, recruitment and retention would suffer because those inclined to join the military would prefer to fly manned aircraft instead of unmanned aircraft. This may be the case in some instances. The future impact of DOD's UAS programs on recruitment, however, is more complicated than this argument suggests.

The recruitment and retention situation varies among the services and for different types of personnel. The Air Force and Navy are actively trying to reduce their number of uniformed personnel. Thus, possible reduced enlistments due to increased UAS use might not have the anticipated negative impact.[97]

A central question related to the potential impact of increased UAS employment on personnel is "what qualifications are required to operate UAS?" Currently, the Air Force requires Predator and Global Hawk operators to be pilot-rated officers. Other services do not require that status for their UAS operators. This means that, in the other services, there is no competition between manned and unmanned aircraft for potentially scarce pilots.

Many people enlist in military service with no desire, or intention to fly manned aircraft. Some wish to fly, but lack physical qualifications, such as good eyesight. The increased fielding of UAS may encourage some to enlist because it offers them an opportunity to "fly" that they may not have had otherwise. Further, those inclined to fly manned aircraft may not be as disinclined to fly UAS as was believed in the past. Flying armed UAS may be more appealing to these personnel than is flying non-armed UAS. Also, flying UAS may be an attractive compromise for certain personnel. While it may not confer all the excitement of flying a manned aircraft, it also avoids many of the hardships (e.g. arduous deployments and potential harm). The Air Force believes that flying UAS from control stations in the United States will be attractive to some in the reserve component who may be disinclined to experience an active duty lifestyle consistent with flying manned aircraft. Also, not all UAS compete with manned aircraft for pilots. Those UAS that are pre-programmed and operate autonomously (like Global Hawk) do not require a pilot, unlike the Predator and other remotely piloted aircraft.

[95] John A. Tirpak, "The RPA Boom," *Air Force*, August 2010.

[96] Currently the Air Force is the only service to require rated pilots to fly their UAVs.

[97] For more information on recruitment issues see CRS Report RL32965, *Recruiting and Retention: An Overview of FY2009 and FY2010 Results for Active and Reserve Component Enlisted Personnel*, by Lawrence Kapp.

2999 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The Air Force maintains that their UAS are more technologically and operationally sophisticated than other UAS, and a trained pilot is required to employ these UAS most effectively. As UAS autonomy, or command and control matures, or if personnel issues for the Air Force become more troublesome, it, or Congress, may decide to review the policy of requiring pilot-rated officers to operate UAS.[98]

Increased employment of UAS could potentially boost enlistment in other specialties, if they are perceived as being effective in their missions. If, for example, those inclined to enlist in infantry positions perceive UAS to offer improved force protection and CAS capabilities over today's manned aircraft, these potential recruits may have fewer qualms about the potential hazards of combat.

Industrial Base Considerations

Defense industrial base issues perennially confront Congress. Is U.S. industry becoming too dependent on foreign suppliers? Do foreign competitors get government subsidies that put U.S. firms at a competitive disadvantage? Should Congress take steps to encourage or discourage defense industry consolidation? Should Congress take steps to promote competition in the defense industrial base? Should Congress takes steps to protect U.S. defense industries in order to safeguard technologies or processes critical to national defense?[99] It appears that DOD's pursuit of UAS presents several interrelated issues relevant to the defense industrial base.

Some commentators argue that increasing acquisition of UAS may take funds from manned aircraft programs, and the technical expertise required to design and perhaps build manned combat aircraft could erode. Many observers point out that the ability to produce world class combat aircraft is a distinct U.S. comparative advantage, and should be guarded closely. Others disagree that the pursuit of UAS could harm the industrial base. They argue that the F-35 Joint Strike Fighter (JSF) is likely to be the last manned tactical fighter, and that the industrial base is naturally evolving toward the skills and processes required to make increasingly advanced UAS.

Those who fear manned industrial base atrophy argue that the future of UAS is overrated, and that demand will continue for tactical manned aircraft in the post-JSF timeframe. In their eyes, crucial skills and technologies could thus be lost by concentrating only on unmanned aircraft design, possibly causing U.S. dominance in tactical aircraft design to wane. These proponents point out that UAS have been around for almost a century, yet only recently became operationally effective, and are not likely to replace manned aircraft in the near future.[100]

Others disagree, and believe that critical manned aircraft design skills are not jeopardized by increased pursuit of UAS because there is considerable commonality between manned and unmanned combat aircraft. Except for the obvious lack of a cockpit, unmanned combat aircraft may require stealthy airframes, advanced avionics, and high performance engines just like

[98] LtGen Dave Deptula, *The Way Ahead: Remotely Piloted Aircraft in the United States Air Force*, U.S. Air Force, undated briefing, http://www.daytonregion.com/pdf/UAV_Rountable_5.pdf.

[99] See, for example, CRS Report RL31236, *The Berry Amendment: Requiring Defense Procurement to Come from Domestic Sources*, by Valerie Bailey Grasso.

[100] For more information on the arguments for and against future demand of tactical aircraft, see CRS Report RL31360, *Joint Strike Fighter (JSF): Potential National Security Questions Pertaining to a Single Production Line*, by Christopher Bolkcom and Daniel H. Else.

3000 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

manned combat aircraft. Also, major defense contractors have already begun to shift to unmanned aircraft design in order to stay competitive. This is because UAS are beginning to play a prominent role in warfare, as seen in Operations Enduring Freedom and Iraqi Freedom. The same skills and technologies required for building manned aircraft will likely lend themselves to unmanned aviation design as well. Companies that have lost out in recent aviation contracts, such as Boeing and the JSF in 2001, are looking towards unmanned bombers and fighters as prospects for growth. Were Boeing to design manned aircraft in the future, the critical skills needed would still be present, according to this argument. Boeing acquired UAS maker Insitu in 2008.[101] Northrop Grumman Corp., as another example, has created a new business unit to aggressively pursue UAS contracts, and acquired Scaled Composites in 2007 in part for UAS design expertise.[102]

Others would argue that maintaining a healthy U.S. defense industrial base depends, in part, on how well U.S. firms compete for the global UAS market. One survey finds that in 2011, there are 680 different UAS programs world wide, up from 195 in 2005. [103] [104] Another estimates that global UAS expenditures will double from $1.7 billion in 2011 to $3.5 billion in 2020.[105] The global market for combat aircraft alone, at approximately $15.8 billion in 2011, dwarfs the UAS market. But the rate of growth is projected to be much slower, peaking at approximately $21 billion in 2017, and dropping to approximately $19 billion in 2020.[106] Thus, some would argue that much new business is likely to be generated in the UAS market, and if U.S. companies fail to capture this market share, European, Russian, Israeli, Chinese, or South African companies will. From this perspective, capturing this new business, and nurturing industrial expertise in UAS challenge areas (e.g. autonomous flight, control of multiple vehicles, command and control, communications bandwidth) would be an effective way to keep U.S. industry competitive and healthy.

As U.S. companies compete for business in a growing international UAS marketplace, concerns about the proliferation of these systems may grow. Are steps required—and if so, what might they be—to control the spread of UAS? As part of its defense and foreign policy oversight, Congress may examine whether a balance must be struck between supporting legitimate U.S. exports and curbing the spread of UAS technologies to dangerous groups or countries.

Congressional Considerations

Advances in UAS technology and their expanding role in national security lead to a number of possible questions for Congressional consideration. They may include:

[101] Andy Pasztor, "Boeing Aims For Slice Of Fighter-Jet Contract Awarded to Lockheed, But Blow Still Stings," *The Wall Street Journal*, October 29, 2001.

3001 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Funding

Should Congress increase, reduce, or approve DOD's proposed overall funding level for UAS?

Budget impact: How might an increased reliance on UAS affect future DOD funding needs? Would it permit a net reduction in DOD funding requirements for performing a given set of missions, and if so, by how much?

Trade-Offs

If funding constraints require choices to be made among DOD UAS programs, what are some of the key potential choices? Choices may include whether to reduce the number of UAS programs, buy fewer UAS overall, defer purchase of more sophisticated UAS, or other choices.

Measures of Effectiveness

How should the effectiveness of UAS be evaluated? Number of aircraft procured? Number of UAS tracks supported? Area under surveillance by UAS? Suppression or elimination of a particular threat or category of threats?

Pace of Effort

In terms of developing, procuring, and integrating UAS into their operations, are DOD and the services moving too slowly, too quickly, or at about the right speed? Are the services adequately implementing their UAS road maps? Should the current requirement for issuing road maps every two years be changed, and if so, how? Can a standard metric be established to determine the optimal pace?

Management

Who should manage the development and procurement of DOD UAS? Should management of at least some of these programs be centralized? If so, where in DOD should the central authority reside?

Air Force Chief of Staff General Norton Schwartz made the case that "Ideally, what you want to do is have the U.S. government together in a way that allows us to get the best capability… An example is BAMS and Global Hawk. Why should the Navy and Air Force have two separate depots, ground stations and training pipelines for what is essentially the same airplane with a different sensor? I think there is lots of opportunity for both of us to make better uses of resources."[107]

3002 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Operators

Are current service policies regarding who can operate a UAS satisfactory? If not, how should they be changed? Should there be a uniform, DOD-wide policy? Should DOD consider using a mix of uniformed and civilian personnel for operating UAS, particularly those that are not used for firing weapons (somewhat similar to how Military Sealift Command ships are operated by a mix of uniformed and civilian personnel)? What would be the potential advantages and disadvantages of such an arrangement for operating UAS? What is an appropriate role for contractors in operating military UAS?

R&D Priorities

What new UAS capabilities are most needed? Should priority be given to incremental increases in capability versus ambitious technological leaps? What is the importance of maintaining the U.S. technological lead in UAS?

Development Facilities

Are current FAA limits on DOD access to domestic U.S. flight facilities for developing UAS hindering the development of DOD UAS? What are the relevant factors and capabilities involved, and do they make a persuasive case for the change or retention of current limits?

Other Issues

In recent years, the pace of UAS development has accelerated, and the scope of UAS missions and applications has expanded. How should these efforts be managed so that they are cost-efficient, effective, and interoperable? In its eagerness to deploy UAS, does DOD risk duplication of effort between various programs? Are DOD UAS acquisition plans responsive to congressional direction? Are UAS being developed fast enough? Are they being developed too fast? Has DOD developed an appropriate plan and structure for incorporating UAS into future military capabilities?

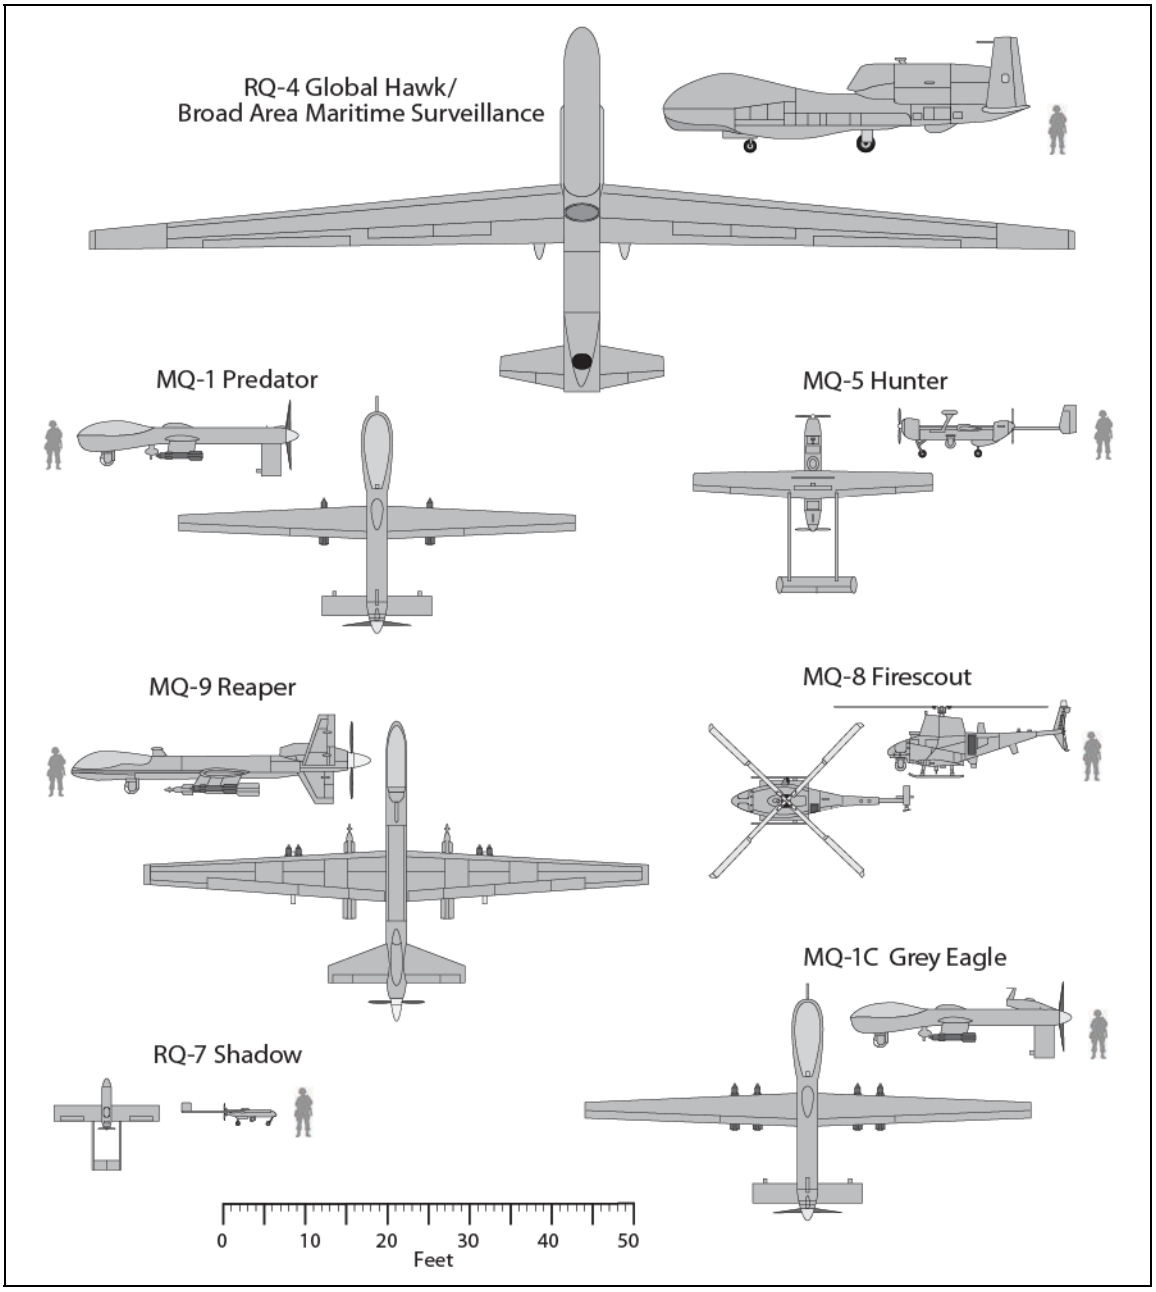
Investment priorities could change as the introduction of UAS into the U.S. inventory shifts the balance between manned and unmanned capabilities. Congress, as part of its defense oversight responsibilities, may assess DOD's current UAS efforts to verify that they match up with new investment goals and strategies. Conventional wisdom states that UAS are cheap, or cost-effective. Is this true today? How do UAS costs compare to manned aircraft costs?

In Summation

UAS have traditionally been used for reconnaissance and surveillance, but today they are being employed in roles and applications that their designers never envisioned. The unanticipated flexibility and capability of UAS have led some analysts to suggest that more, if not most, of the missions currently undertaken by manned aircraft could be turned over to unmanned aerial platforms, and that manned and unmanned aircraft could operate together. Future Congresses may have to contemplate the replacement of a significant portion of the manned aircraft fleet with unmanned aircraft.

3003 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Current Major DOD UAS Programs



This section addresses the program status and funding of some of the most prominent UAS programs being pursued by DOD, and most likely to compete for congressional attention. This section does not attempt to provide a comprehensive survey of all UAS programs, nor to develop a classification system for different types of UAS (e.g. operational vs. developmental, single mission vs. multi mission, long range vs. short range). One exception is a short subsection below titled "Small UAVs." The UAVs described in this section are distinguished from the proceeding UAVs by being man-portable and of short range and loiter time. These smaller UAVs are not currently, and are unlikely to be, weaponized. The Services do not provide as detailed cost and budget documentation for these UAVs as they do for major UAS programs. Individually, these UAVs appear very popular with ground forces, yet do not necessarily demand as much congressional attention as larger UAS programs like Predator or Global Hawk. As a whole, however, these small, man-portable UAVs appear likely to increasingly compete with major UAS programs for congressional attention and funding.

Table 6. Characteristics of Selected Tactical and Theater-Level Unmanned Aircraft

System	Length (ft)	Wingspan (ft)	Gross weight (lbs)	Payload capacity (lbs)	Endurance (hours)	Maximum altitude (ft)
Predator	27	55	2,250	450	24+	25,000

Source: Congressional Budget Office based on data from the Department of Defense's budget request for 2012, Selected Acquisition Reports for December 2010, and Aircraft Procurement Plan: Fiscal Years 2012-2041 (submitted with the 2012 budget, March 2011).

Notes: Acquisition cost includes the cost of procuring air vehicles, sensors, and grounds stations, plus the cost for research. development, test, and evaluation. The services' cost data have been adjusted using CBO's projection of inflation and rounded to the nearest $10 million.

a. The Department of Defense has no plans to acquire or modify the specified system in these years.

b. The cost is for the follow-on aircraft the Air Force plans to acquire instead of the Reaper.

MQ-1 Predator

Through its high profile use in Iraq and Afghanistan and its multi-mission capabilities, the MQ-1 Predator has become the Department of Defense's most recognizable UAS. Developed by General Atomics Aeronautical Systems in San Diego, CA, the Predator has helped to define the modern role of UAS with its integrated surveillance payload and armament capabilities. Consequently, Predator has enjoyed accelerated development schedules as well as increased

3006 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

procurement funding. The wide employment of the MQ-1 has also facilitated the development of other closely related UAS (described below) designed for a variety of missions.

System Characteristics. Predator is a medium-altitude, long-endurance UAS. At 27 feet long, 7 feet high and with a 48 foot wingspan, it has long, thin wings and a tail like an inverted "V". The Predator typically operates at 10,000 to 15,000 feet to get the best imagery from its video cameras, although it has the ability to reach a maximum altitude of 25,000 feet. Each vehicle can remain on station, over 500 nautical miles away from its base, for 24 hours before returning home. The Air Force's Predator fleet is operated by the 15th and 17th Reconnaissance Squadrons out of Creech Air Force Base, NV; the 11th Reconnaissance Squadron provides training. A second control station has been established at Whiteman AFB, MO.[108] Further, "[t]here are plans to set up Predator operations at bases in Arizona, California, New York, North Dakota, and Texas."[109] The Air Force has about 175 Predators;[110] the CIA reportedly owns and operates several Predators as well.

Mission and Payload. The Predator's primary function is reconnaissance and target acquisition of potential ground targets. To accomplish this mission, the Predator is outfitted with a 450-lb surveillance payload, which includes two electro-optical (E-O) cameras and one infrared (IR) camera for use at night. These cameras are housed in a ball-shaped turret that can be easily seen underneath the vehicle's nose. The Predator is also equipped with a Multi-Spectral Targeting System (MTS) sensor ball which adds a laser designator to the E-O/IR payload that allows the Predator to track moving targets. Additionally, the Predator's payload includes a synthetic aperture radar (SAR), which enables the UAS to "see" through inclement weather. The Predator's satellite communications provide for beyond line-of-sight operations. In 2001, as a secondary function, the Predator was outfitted with the ability to carry two Hellfire missiles. Previously, the Predator identified a target and relayed the coordinates to a manned aircraft, which then engaged the target. The addition of this anti-tank ordinance enables the UAS to launch a precision attack on a time sensitive target with a minimized "sensor-to-shoot" time cycle. Consequently, the Air Force changed the Predator's military designation from RQ-1B (reconnaissance unmanned) to the MQ-1 (multi-mission unmanned).[111] The air vehicle launches and lands like a regular aircraft, but is controlled by a pilot on the ground using a joystick.

MQ-1C Grey Eagle

A slightly larger, longer-endurance version of the Predator, the Army's MQ-1C Grey Eagle entered low-rate initial production on March 29, 2010.[112] The Grey Eagle can remain aloft for 36 hour, 12 hours longer than its Air Force sibling.

An Army platoon operates four (4) aircraft with electro-optical/infrared and/or laser rangefinder/designator payloads, communications relay equipment, and up to four Hellfire

3007 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

missiles. Each platoon includes two ground control stations, two ground data terminals, one satellite communication ground data terminal, one portable ground control station, one portable ground data terminal, an automated takeoff and landing system, two tactical automatic landing systems, and ground support equipment. In total, the program will be 124 aircraft, plus 21 attrition aircraft and seven schoolhouse aircraft, for a total of 152 aircraft. The average procurement unit cost of a Grey Eagle system is $114.1 million.[113]

MQ-9 Reaper

The MQ-9 Reaper, formerly the "Predator B," is General Atomics' follow on to the MQ-1. The Reaper is a medium-to-high altitude, long endurance Predator optimized for surveillance, target acquisition and armed engagement. While the Reaper borrows from the overall design of the Predator, the Reaper is 13 feet longer and carries a 16-foot-longer wingspan. It also features a 900hp turboprop engine, which is significantly more powerful than the Predator's 115hp engine. These upgrades allow the Reaper to reach a maximum altitude of 50,000 feet, a maximum speed of 225 knots, a maximum endurance of 32 hours and a maximum range of 2000 nautical miles.[114] However, the feature that most differentiates Reaper from its predecessor is its ordinance capacity. While the Predator is outfitted to carry two 100-pound Hellfire missiles, the Reaper now can carry as many as 16 Hellfires, equivalent to the Army's Apache helicopter, or a mix of 500-pound weapons and Small Diameter Bombs.

As of February 4, 2011, General Atomics Aeronautical Systems had delivered 65 of 399 planned Reapers, 43 of which are operationally active.[115]

The MQ-9 is operated by the 17th Reconnaissance Squadron and the 42nd Attack Squadron, both at Creech Air Force Base, Nevada, and the 29th Attack Squadron at Holloman AFB, New Mexico. [116]

Program Status. Predator–family UAS are operated as part of a system, which consists of four air vehicles, a ground control station, and a primary satellite link. The unit cost in FY2009 for one Predator system was approximately $20 million,[117] while the average procurement unit cost for a Reaper system was $26.8 million.[118]

RQ-4 Global Hawk

Northrop Grumman's RQ-4 Global Hawk has gained distinction as the largest and most expensive UAS currently in operation for the Department of Defense. Global Hawk incorporates a diverse surveillance payload with performance capabilities that rival or exceed most manned spy planes. However, Pentagon officials and members of Congress have become increasingly concerned with the program's burgeoning cost, which resulted in Nunn-McCurdy breaches in April 2005, and April 2011.[119] Also, the RQ-4B Block 30 was deemed "not operationally suitable" due to "low air vehicle reliability" by the office of Operational Test and Evaluation in May 2011.[120] [121]

System Characteristics. At 44 feet long and weighing 26,750 lbs, Global Hawk is about as large as a medium sized corporate jet. Global Hawk flies at nearly twice the altitude of commercial airliners and can stay aloft at 65,000 feet for as long as 35 hours. It can fly to a target area 5,400 nautical miles away, loiter at 60,000 feet while monitoring an area the size of that state of Illinois for 24 hours, and then return. Global Hawk was originally designed to be an autonomous drone capable of taking off, flying, and landing on pre-programmed inputs to the UAV's flight computer. Air Force operators have found, however, that the UAS requires frequent intervention by remote operators.[122] The RQ-4B resembles the RQ-4A, yet features a significantly larger airframe. In designing the B-model, Northrop Grumman increased the Global Hawk's length from 44 feet to 48 feet and its wingspan from 116 feet to 132 feet. The expanded size enables the RQ-4B to carry an extra 1000 lbs. of surveillance payload.

[119] Amy Butler, "USAF Declares Second Major Global Hawk Cost Breach," Aerospace Daily, April 13, 2011. The 2005 breach stemmed from costs in transitioning from the Block 10 Global Hawk to the larger Block 30; the 2011 breach was attributed primarily to reduced procurement quantities rather than issues with the program.

3009 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Mission and Payload. The Global Hawk UAS has been called "the theater commander's around-the-clock, low-hanging (surveillance) satellite."[123] The UAS provides a long-dwell presence over the battlespace, giving military commanders a persistent source of high quality imagery that has proven valuable in surveillance and interdiction operations. The RQ-4A's current imagery payload consists of a 2,000-lb integrated suite of sensors much larger than those found on the Predator. These sensors include an all-weather SAR with Moving Target Indicator (MTI) capability, an E-O digital camera and an IR sensor. As the result of a January 2002 Air Force requirements summit, Northrop Grumman expanded its payload to make it a multi-intelligence air vehicle. The subsequent incarnation, the RQ-4B, is outfitted with an open-system architecture that enables the vehicle to carry multiple payloads, such as signals intelligence (SIGINT) and electronic intelligence (ELINT) sensors. Furthermore, the classified Multi-Platform Radar Technology Insertion Program (MP-RTIP) payload will be added in order to increase radar capabilities. These new sensor packages will enable operators to eavesdrop on radio transmissions or to identify enemy radar from extremely high altitudes. Future plans include adding hyper-spectral sensors for increased imagery precision and incorporating laser communications to expand information transfer capabilities.[124] The end goal is to field a UAS that will work with space-based sensors to create a "staring net" that will prevent enemies from establishing a tactical surprise.[125] In August of 2003, the Federal Aviation Administration granted the Global Hawk authorization to fly in U.S. civilian airspace, which further expanded the system's mission potential.[126] This distinction, in combination with the diverse surveillance capabilities, has led many officials outside the Pentagon to consider the Global Hawk an attractive candidate for anti-drug smuggling and Coast Guard operations.[127]

Program Status. Developed by Northrop Grumman Corporation of Palmdale, CA, Global Hawk entered low-rate-initial-production in February 2002. The Air Force has stated that it intends to acquire 51 Global Hawks, at an expected cost of $6.6 billion for development and procurement costs. As of November 2009, the Air Force possessed 7 RQ-4A s and 3 RQ-4Bs. [128] Another 32 Global Hawks had been authorized and appropriated through FY2011. [129] According to the most recent Selected Acquisition Report, the current average procurement unit cost for the Global Hawk has reached $140.9 million in current dollars.[130]

In April 2005, the Air Force reported to Congress that the program had overrun by 18% as a result of an "increasing aircraft capacity to accommodate requirements for a more sophisticated, integrated imagery and signals intelligence senor suite".[131] A Government Accountability Office report in December 2004 noted that the program had increased by nearly $900 million since 2001 and recommended delaying the purchase of future Global Hawks until an appropriate

3010 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

development strategy could be implemented.[132] The rising costs of the UAV and accusations of Air Force mismanagement have caused concern among many in Congress and in the Pentagon as well as facilitating an overall debate on the Air Force's development strategy.[133]

Following a 2010 Defense Acquisition Board review of the Global Hawk program,

> Air Force acquisition executive David Van Buren told reporters that he is "not happy" with the pace of the program, both on the government and the contractor side. Chief Pentagon arms buyer Ashton Carter also criticized the program, saying that it was "on a path to being unaffordable."[134]

In April, 2011, a reduction in the number of Global Hawk Block 40 aircraft requested in the FY2012 budget from 22 to 11 caused overall Global Hawk unit prices to increase by 11%, again triggering Nunn-McCurdy.[135]

In its markup of the Fiscal 2011 defense authorization bill, the House Armed Services Committee expressed concern "that differing, evolving service unique requirements, coupled with Global Hawk UAS vanishing vendor issues, are resulting in a divergence in each service's basic goal of maximum system commonality and interoperability, particularly with regard to the communications systems." The bill report directs the Under Secretary of Defense for Acquisition, Technology and Logistics to certify and provide written notification to the congressional defense committees by March 31, 2011, that he has reviewed the communications requirements and acquisition strategies for both Global Hawk and BAMS. The subcommittee wants assurance that the requirements for each service's communications systems have been validated and that the acquisition strategy for each system "achieves the greatest possible commonality and represents the most cost effective option" for each program.[136]

A May 20, 2011 report from the Air Force Operational Test and Evaluation Center found the Global Hawk Block 20/30 to be "effective with significant limitations ... not suitable and partially mission capable." The report cited "lackluster performance of the EISS imagery collector and ASIP sigint collectors at range" rather than issues with the Global Hawk airframe itself.[137]

BAMS

The Navy's Broad Area Maritime Surveillance system is based on the Global Hawk Block 20 airframe but with significantly different sensors from its Air Force kin. This, coupled with a smaller fleet size, results in a higher unit cost. "The air service's drone costs $27.6 million per copy, compared to an expected $55 million per BAMS UAV, including its sensors and communications suite... At 68 aircraft, the BAMS fleet will be the world's largest purchase of long-endurance marinized UAVs."[138]

System Characteristics and Mission. "BAMS ... provides persistent maritime intelligence, surveillance, and reconnaissance data collection and dissemination capability to the Maritime Patrol and Reconnaissance Force. The MQ-4C BAMS UAS is a multi-mission system to support strike, signals intelligence, and communications relay as an adjunct to the MMA/P-3 community to enhance manpower, training and maintenance efficiencies worldwide."[139]

"The RQ-4 ... features sensors designed to provide near worldwide coverage through a network of five orbits inside and outside continental United States, with sufficient air vehicles to remain airborne for 24 hours a day, 7 days a week, out to ranges of 2000 nautical miles. Onboard sensors will provide detection, classification, tracking and identification of maritime targets and include maritime radar, electro-optical/infra-red and Electronic Support Measures systems. Additionally, the RQ-4 will have a communications relay capability designed to link dispersed forces in the theater of operations and serve as a node in the Navy's FORCEnet strategy."[140]

3012 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

"The drones ... will collect information on enemies, do battle-damage assessments, conduct port surveillance and provide support to Navy forces at sea. Each aircraft is expected to serve for 20 years." [141]

Program Status. The Administration's FY2012 budget request documents place Milestone C for BAMS in the 3rd quarter of FY2013, with initial operational capability in the 1st quarter of 2016. "Since Milestone B for the Navy BAMS UAS program, identifying opportunities for the RQ-4-based BAMS and Global-Hawk programs has been a significant interest item for the UAS TF and has been well documented within the Department." [142] In one effort to integrate development, on June 12, 2010, the Navy and Air Force concluded a Memorandum of Agreement (MOA) regarding their Global Hawk and BAMS programs, which use a common airframe. "Shared basing, maintenance, command and control, training, logistics and data exploitation are areas that could be ripe for efficiencies, says Lt. Gen David Deptula, Air Force deputy chief of staff for intelligence, surveillance and reconnaissance… Also, a single pilot and maintenance training program is being established at Beale AFB, Calif., for both fleets."[143] However, issues still exist over common control stations and whether one service's pilots should be able to operate the other service's aircraft.

MQ-8B Fire Scout

Now in deployment, the Fire Scout was initially designed as the Navy's choice for an unmanned helicopter capable of reconnaissance, situational awareness and precise targeting.[144] Although the Navy canceled production of the Fire Scout in 2001, Northrop Grumman's vertical take-off UAV was rejuvenated by the Army in 2003, when the Army designated the Fire Scout as the interim Class IV UAV for the future combat system. The Army's interest spurred renewed Navy funding for the MQ-8, making the Fire Scout DOD's first joint UAS helicopter.

System Characteristics and Mission. Northrop Grumman based the design of the Fire Scout on a commercial helicopter. The RQ-8B model added a four-blade rotor to reduce the aircraft's acoustic signature.[145] With a basic 127-lb. payload, the Fire Scout can stay aloft for up to 9.5 hours; with the full-capacity sensor payload, endurance diminishes to roughly six hours. Fire Scout possesses autonomous flight capabilities. The surveillance payload consists of a laser designator and range finder, an IR camera and a multi-color EO camera, which when adjusted with specific filters could provide mine-detection capabilities.[146] Fire Scout also currently possesses line-of-sight communication data links. Initial tests of an armed Fire Scout were conducted in 2005, and the Navy expects to add "either Raytheon's Griffin or BAE's Advanced Precision Kill Weapon System" small missiles to currently deployed Fire Scouts soon.[147]

3013 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Discussions of future missions have also covered border patrol, search and rescue operations, medical resupply and submarine spotting operations.

Program Status. Six production MQ-8 air vehicles have been delivered to date.[148] The Pentagon's 2009 UAS Roadmap estimates a future inventory of 131 RQ-8Bs for the Navy to support the Littoral Combat Ship class of surface vessels.[149] [150] The Army had intended to use the Fire Scout as the interim brigade-level UAV for its Future Combat System program,[151] but canceled its participation in January, 2010.[152]

A Fire Scout attracted media attention in August, 2010, when it flew through Washington, D.C. airspace after losing its control link. "A half-hour later, Navy spokesmen said, operators re-established control and the drone landed safely."[153]

FIRE-X/MQ-8C

The FIRE-X project, recently designated MQ-8C but continuing the Fire Scout name, is a developmental effort to adapt the Fire Scout software and navigation systems to a full-size standard helicopter. The Navy "is to award Northrop Grumman a contract to supply 28 MQ-8C Fire Scout ... to be fielded by the first quarter of 2014 to meet an urgent operational requirement."[154]

> Fire Scout can fly for 8 hours with a maximum range of 618 nautical miles? Well, Fire-X will fly for 15, with a max range of 1227. Fire Scout tops out at 100 knots? Fire-X can speed by at 140. Fire-X will carry a load of 3200 lbs. to Fire Scout's 1242. All this talk from a drone helicopter that just took its first flight in December.... Fire-X isn't going to be a big departure from Fire Scout, though. The BRITE STAR II and other radars will remain on board, as will its software for relaying information to a ship.[155]

RQ-170 Sentinel

Although publicly acknowledged to exist, most information about the Lockheed Martin RQ-170 Sentinel is classified. First photographed in the skies over Afghanistan, but also reportedly in operation from South Korea,[156] the RQ-170 is a tailless "flying wing" stealthier than other current

3014 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

US UAS. An RQ-170 was reported to have performed surveillance and data relay related to the operation against Osama bin Laden's compound on May 1, 2011. The government of Iran claimed on December 2, 2011 to be in possession of an intact RQ-170 following its incursion into Iranian airspace.

System Characteristics. Built by Lockheed Martin, the RQ-170 has a wingspan of about 65 feet and is powered by a single jet engine. It appears to have two sensor bays (or satellite dish enclosures) on the upper wing surface. Although an inherently low-observable blended wing/fuselage design like the B-2, the RQ-170's conventional inlet, exhaust, and landing gear doors suggest a design not fully optimized for stealth.[157]

Potential Mission and Payload. "The RQ-170 will directly support combatant commander needs for intelligence, surveillance and reconnaissance to locate targets."[158]

Program Status. "The RQ-170 is a low observable unmanned aircraft system (UAS) being developed, tested and fielded by the Air Force."[159] No further official status is available.

Other Current UAS Programs

RQ-5A Hunter / MQ-5B Hunter II

Originally co-developed by Israel Aircraft Industries and TRW (now owned by Northrop Grumman) for a joint U.S. Army/Navy/Marine Corps short range UAS, the Hunter system found a home as one of the Army's principal unmanned platforms. The service has deployed the RQ-5A for tactical ISR in support of numerous ground operations around the world. At one time, the Army planned to acquire 52 Hunter integrated systems of eight air vehicles apiece, but the Hunter program experienced some turbulence. The Army canceled full-rate-production of the RQ-5A in 1996, but continued to use the seven systems already produced. It acquired 18 MQ-5B Hunter IIs through low-rate-initial-production in FY2004 and FY2005. The MQ-5B's design includes longer endurance and the capability to be outfitted with anti-tank munitions. Both variants are currently operated by the 224th Military Intelligence Battalion out of Fort Stewart, GA; by the 15th Military Intelligence Battalion out of Ft. Hood, TX; and by 1st Military Intelligence Battalion out of Hohenfels, Germany.

System Characteristics. The RQ-5A can fly at altitudes up to 15,000 feet, reach speeds of 106 knots, and spend up to 12 hours in the air. Weighing 1,600 lbs, it has an operating radius of 144 nautical miles. The MQ-5B includes an elongated wingspan of 34.3 feet up from 29.2 feet of the RQ-5A and a more powerful engine, which allows the Hunter II to stay airborne for three extra hours and to reach altitudes of 18,000 feet.[160] The Hunter system consists of eight aircraft, ground control systems and support devices, and launch/recovery equipment. In FY2004, the final year of Hunter procurement, a Hunter system cost $26.5 million.

3015 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Mission and Payload. The Army has mostly used the Hunter system for short and medium range surveillance and reconnaissance. More recently, however, the Army expanded the Hunter's missions, including weaponization for tactical reconnaissance/strike operations with the GBU-44/B Viper Strike precision guided munition, which can designate targets either from the munition's laser, from another aerial platform or from a ground system. This weapon makes the Hunter the Army's first armed UAS. "Also, in 2004, the Department of Homeland Security, Customs and Border Protection Bureau, and Office of Air and Marine utilized Hunter under a trial program for border patrol duties. During this program, the Hunter flew 329 flight hours, resulting in 556 detections."[161]

Program Status. The Army halted Hunter production in 2005. As of May 2011, 45 Hunter UAVs were still in operation and periodically receiving upgrades and modifications. In August, 2005, the Army awarded General Atomics' Warrior UAS (which later became Grey Eagle) the contract for the Extended Range-Multi Purpose UAS program over the Hunter II.[162]

RQ-7 Shadow

The RQ-7 Shadow found a home when the Army, after a two decade search for a suitable system, selected AAI's close range surveillance platform for its tactical unmanned aerial vehicle (TUAV) program. Originally, the Army, in conjunction with the Navy explored several different UAVs for the TUAV program, including the now-cancelled RQ-6 Outrider system. However, in 1997 after the Navy pursued other alternatives, the Army opted for the low cost, simple design of the RQ-7 Shadow 200. Having reached full production capacity and an IOC in 2002, the Shadow has become the primary airborne ISR tool of numerous Army units around the world and is expected to remain in service through the decade.

The Administration's FY2011 budget request did not include funding for Shadow aircraft, although it did include continued RDT&E funding for Shadow.[163]

System Characteristics. Built by AAI Corporation (now owned by Textron), the Shadow is 11 feet long with a wingspan of 13 feet. It has a range of 68 nautical miles, a distance picked to match typical Army brigade operations, and average flight duration of five hours. Although the Shadow can reach a maximum altitude of 14,000 feet, its optimum level is 8,000 feet. The Shadow is catapulted from a rail-launcher, and recovered with the aid of arresting gear. The UAS also possesses automatic takeoff and landing capabilities. The upgraded version, the RQ-7B Shadow, features a 16 inch greater wingspan and larger fuel capacity allowing for an extra two hours of flight endurance.

Mission and Payload. The Shadow provides real-time reconnaissance, surveillance and target acquisition information to the Army at the brigade level. A potential mission for the Shadow is the perilous job of medical resupply. The Army is considering expanding the UAS's traditional missions to include a medical role, where several crucial items such as blood, vaccines and fluid

infusion systems could be delivered to troops via parachute.[164] For surveillance purposes, the Shadow's 60-pound payload consists of an E-O/IR sensor turret which produces day or night video, and can relay data to a ground station in real-time via a line-of-sight data link. As part of the Army's Future Combat System plans, the Shadow will be outfitted with the Tactical Common Data Link currently in development to network the UAS with battalion commanders, ground units and other air vehicles.[165] The Marine Corps is considering how to arm Shadow.[166]

Program Status. The Army and Marine Corps currently maintain an inventory of 364 Shadow UAVs.[167] The program cost for a Shadow UAV system—which includes four vehicles, ground control equipment, launch and recovery devices, remote video terminals, and High Mobility Multipurpose Wheeled Vehicles for transportation-reached $11.1 million in current year dollars for FY2008.[168] The Army procured 102 systems through 2009.[169] In FY2012, the Army requested $25 million for 20 Shadow aircraft to replace combat losses, and approximately $200 million for payload upgrades.

"Small UAVs"

RQ-14 Dragon Eye

AeroVironment's Dragon Eye is a backpack-carried, battery-operated UAV employed by the Marines at the company level and below for reconnaissance, surveillance and target acquisition. Dragon Eye features a 3.8 ft. rectangular wing, twin propellers and two cameras ports each capable of supporting day-light electro-optical cameras, low-light TV cameras, and infrared cameras. The compact and lightweight design of the UAV allows an operational endurance of 45 minutes and can travel as far as two and a half nautical miles from the operator. Low-rate-initial-production of 40 aircraft began in 2001. After a 2003 operational assessment, the Marine Corps awarded AeroVironment a contract to deliver approximately 300 systems of full-rate-production Dragon Eyes.[170] However, that contract was later revised to acquire Raven UAS instead. One Dragon Eye system consists of three air vehicles and one ground station. The final Marine Corps procurement budget request in FY2006 anticipated the current unit cost per Dragon Eye system as $154,000.[171]

3017 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

FQM-151 Pointer

Although procurement of this early UAS began in 1990, the electric-powered Pointer has seen service in Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF). Pointer is a short range reconnaissance and battlefield surveillance UAV developed by AeroVironment. Its flight endurance (two hours) is greater than most similar small UAVs, in part due to its relatively large, 9-foot wingspan. That wingspan decreases portability of the 8.5-pound Pointer, and as a result, transportation of a Pointer system (two air vehicles and a ground control unit) requires two personnel. Although superseded by the Raven (below), Pointer remains a valued short range ISR asset for the Air Force and Special Operations Command.

RQ-11 Raven

Engineered from the basic design of the Pointer, the Raven is two-thirds the size and weight of its predecessor, with a much smaller control station, making the system man-portable.[172] "The RQ-11A is essentially a down-sized FQM-151 *Pointer*, but thanks to improved technology can carry the same navigation system, control equipment, and payload."[173] The Raven provides Army and SOCOM personnel with "over-the-hill" reconnaissance, sniper spotting and surveillance scouting of intended convoy routes. The electric motor initiates flight once hand-launched by a running start from the ground operator. The vehicle is powered by an electric battery that needs to be recharged after 90 minutes, but deployed soldiers are equipped with four auxiliary batteries that can be easily charged using the 28 volt DC outlet in a Humvee. The vehicle lands via a controlled crash in which the camera separates from the body, which is composed of Kevlar plating for extra protection. Like the Pointer, the Raven can carry either an IR or an E-O camera and transmits real-time images to its ground operators. The relatively simple system allows soldiers to be trained in-theater in a matter of days. Raven systems can either be deployed in three aircraft or two-aircraft configurations. "Raven was adopted as the US Army's standardised short range UAV system in 2004 with a total of 2469 air vehicles (including older RQ-11A series models) in operational service by mid 2007."[174] "The US Army has an ongoing acquisition objective for about 2,200 Raven systems and has taken delivery of more than 1,300 to date."[175] A three-aircraft system costs approximately $167,000.[176]

ScanEagle

Developed by the Insitu Group (owned by Boeing) as a "launch-and-forget" UAV, the ScanEagle autonomously flies to points of interest selected by a ground operator.[177] The ScanEagle has gained notice for its long endurance capabilities and relative low cost. The gasoline-powered UAV features narrow 10 foot wings that allow the 40 lb. vehicle to reach altitudes as high as 19,000 feet, distances of more than 60 nautical miles and a flight endurance of almost 20 hours.

3018 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Using an inertially stabilized camera turret carrying both electro-optical and infrared sensors, ScanEagle currently provides Marine Corps units in Iraq with force-protection ISR and is also used by Special Operations Command. ScanEagle operations began in 2004,[178] and continue today. Although ScanEagle was expected to cost about $100,000 per copy, the Navy and SOCOM have contracted for operations instead of procurement, with Boeing providing ISR services utilizing ScanEagle under a fee-for-service arrangement.[179]

ScanEagle is also in use by non-military organizations for surveillance purposes including tracking whale migrations.[180]

Small Tactical Unmanned Aerial System (STUAS)

In July 2010, the Department of the Navy awarded Insitu a two-year, $43.7 million contract for the design, development, integration, and test of the Small Tactical Unmanned Aircraft System (STUAS) for use by the Navy and Marine Corps to provide persistent maritime and land-based tactical reconnaissance, surveillance, and target acquisition (RSTA) data collection and dissemination. "For the USMC, STUAS will provide the Marine Expeditionary Force and subordinate commands (divisions and regiments) a dedicated ISR system capable of delivering intelligence products directly to the tactical commander in real time. For the Navy, STUAS will provide persistent RSTA support for tactical maneuver decisions and unit-level force defense/force protection for Navy ships, Marine Corps land forces, and Navy Special Warfare Units." [181]

Payloads include day/night video cameras, an infrared marker, and a laser range finder, among others. STUAS can be launched and recovered from an unimproved expeditionary/urban environment, as well as from the deck of Navy ships.[182]

STUAS uses Insitu's Integrator airframe, which uses common launch, control, and recovery equipment with ScanEagle. STUAS has a takeoff weight of up to 125 pounds with a range of 50 nautical miles. However, STUAS will be procured and operated by the services rather than operated on a fee-for-service basis because "the Scan Eagle's current fee-for-service contract limits the way the UAS is deployed ... with Boeing/Insitu employees usually operating the aircraft in the field due to liability issues." Procuring the system will allow the services to train their own operators. Initial operating capability is expected in the fourth quarter of FY2013. [183]

3019 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Future UAS

Unmanned Carrier-Launched Airborne Surveillance and Strike (UCLASS)

In the mid 1990s, the Pentagon began developing a UAS designed primarily for combat missions. The result was two separate Unmanned Aerial Combat Vehicles (UCAV) programs, the Air Force's UCAV and the Navy's UCAV-N demonstrator program. The Air Force favored Boeing's X-45 for its program, while Northrop Grumman's X-47 Pegasus and Boeing's X-46 competed for the Navy's project. However, in June 2003, the Pentagon merged the two programs in order to establish the Joint Unmanned Combat Air System (J-UCAS) project under the management of the Defense Advanced Research Projects Agency (DARPA). The objective of the J-UCAS merger was to create a flexible offensive network in which the air and ground elements are adapted to meet specific combat mission.[184] As part of Program Budget Decision (PBD) 753 in December 2004, DARPA was ordered to transfer administration of the J-UCAS resources to Air Force.[185] J-UCAS was cancelled in 2006. The total money spent on the J-UCAS/UCAV program, which reached more than $1.45 billion in RDT&E funding, made it one of the most expensive UAS ventures undertaken by DOD.

Subsequently, in May, 2010, the Navy issued a Request for Information for a carrier-borne UCAV called UCLASS,

> seeking ideas on a stealthy strike/surveillance platform that could operate alongside manned aircraft as part of a carrier air wing by the end of 2018. The notional system would comprise four to six aircraft capable of autonomous operation from Nimitz- and Ford-class carriers, with an unrefueled endurance of 11-14 hours and the capability for both hose-and-drogue and boom-and-probe aerial refueling. [186]

Another significant attribute of UCLASS is that—unlike most current UAS that are designed to operate only in permissive or lightly defended environments—UCLASS "must be capable of operating in hostile airspace, which means the aircraft design must feature low-observable traits."[187] Navy Secretary Ray Mabus said that "The notion here is that—just like the F-35 carrier version—it is going to be stealthy. It is going to be low observable," he says. "And, if you are going to integrate an airplane into the carrier air wing, it should be able to go into contested airspace."[188]

The Navy has awarded UCLASS concept study contracts to Boeing, General Atomics Aeronautical Systems, Lockheed Martin, and Northrop Grumman.[189] The UCLASS request for proposal is expected in fall 2011.[190]

3020 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Likely UCLASS contenders include the following:

X-47B

Northrop Grumman's X-47B, an advanced version of the X-47A UCAV-N contender, is nearly 36 feet long, with a wingspan of 62 feet. The increased wingspan in combination with the Pratt & Whitney F100-220U turbojet engine may allow X-47B an endurance of nine hours and range of 1,600 nautical miles. The X-47B features folding wing-tips that cut down on size, making it more suitable for storage aboard an aircraft carrier.[191]

Phantom Ray

System Characteristics. 36 feet long with a wingspan of 50 feet; single GE F404-102D engine. The X-45C was expected to achieve speeds of 450 knots and altitudes of 40,000 feet, with a flight duration of up to seven hours and a range of 1,200 nautical miles.

Program Status. First flown on May 27, 2011, Phantom Ray is a development of Boeing's X-45C J-UCAS contender. Although it is a company-funded one-off demonstrator, it is expected to contend for the Navy's UCLASS program.

Avenger/Sea Avenger

General Atomics is currently developing a third generation Predator that uses a turbojet engine to fly long endurance, high altitude surveillance missions. The Avenger (formerly "Predator C") will reportedly use the fuselage of the Reaper, but will be similar to Northrop Grumman's Global Hawk in payload capacity and flight performance. General Atomics confirmed its offer of the "Sea Avenger" variant for the UCLASS competition in 2010.[192]

> With a 41-foot long fuselage and 66-foot wingspan, the Avenger is capable of staying in the air for up to 20 hours, and operating at up to 50,000 feet. Powered by a 4,800-lb. thrust Pratt & Whitney PW545B jet engine, it can fly at over 400 knots—50 percent faster than the turboprop-powered Reaper unmanned plane, and more than three times as quick as the Predator.
>
> General Atomics says the first Avenger is now flying two to three times a week.... A second and third Avenger are now in production. It'll be a little longer than the first—44 feet—and able to haul a 6,000 pound payload. That's a 50 percent improvement over what the Reaper can carry.[193]

Lockheed is also reported to be interested in entering an RQ-170 variant in the UCLASS competition.[194]

3021 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

High Altitude Long Endurance Systems

Tactical UAS, ranging from Raven to Reaper, have become familiar, and the prototypes of combat UAS like UCLASS are already in the air. But a new class of UAS is under development that would move beyond the endurance and range of Global Hawk to provide much more persistent platforms for ISR, data relay, and other purposes. Among these HALE, for high altitude long endurance systems, are:

Phantom Eye

Proposed by the Boeing Phantom Works, Phantom Eye would use hydrogen-fueled automobile engines to carry a 3,000-pound payload for ten days.[195] A 150-foot wingspan demonstrator version hopes to achieve "up to four days of endurance at 65,000 ft." with a first flight in autumn 2011.[196]

Orion

In 2009, Aurora Flight Sciences unveiled the Orion, which would use hydrogen-fueled diesel engines to carry a 2,600-pound payload at 30,000 feet, or a 1,000-pound payload for ten days at 15,000-20,000 feet.[197] [198] Its demonstrator version is designed to reach five-day endurance with the same payload.[199] Orion is part of a system called MAGIC, an acronym for Medium-Altitude Global ISR and Communications, being developed by under a $4.7-million contract from the Air Force Research Laboratory.[200]

Global Observer

A third hydrogen-powered HALE contender, AeroVironment's Global Observer "can fly as high as 65,000 feet for five to seven days while carrying a 400-pound payload."[201] It is optimized for "persistent communications and remote sensing."[202] Global Observer flew for the first time in 2010, but the first test aircraft crashed in April, 2011.

Airships

Several firms (Lockheed Martin, MAV6, Northrop Grumman, and others) are developing unmanned airships for long- to extremely-long endurance missions. "In comparison with unmanned fixed-wing aircraft, such as the Global Hawk or Reaper, an airship ... would have a

Army Unmanned Aircraft Systems

Corps Level

Corps Level reconnaissance, surveillance, target acquisition, and battle damage assessment

Division Level

Provide dedicated mission configured, UAV support to the Combat Aviation Brigade, Division Fires and Battlefield Surveillance Brigades, Brigade Combat Teams (BCTs), and other Army and Joint Force units based upon Division Commander's priorities

Brigade Level

Provide Army Brigade Commanders with tactical level reconnaissance, surveillance, target acquisition, and battle damage assessment

Battalion Level

Provides the small unit the organic capability to perform Beyond Visual Line-Of-Sight (BLOS) Reconnaissance, Surveillance, and Target Acquisition (RSTA)

FOCUS OF ARMY UAS:

- ~~Strategic~~
- Operational
- Tactical

Hunter
MQ-5B

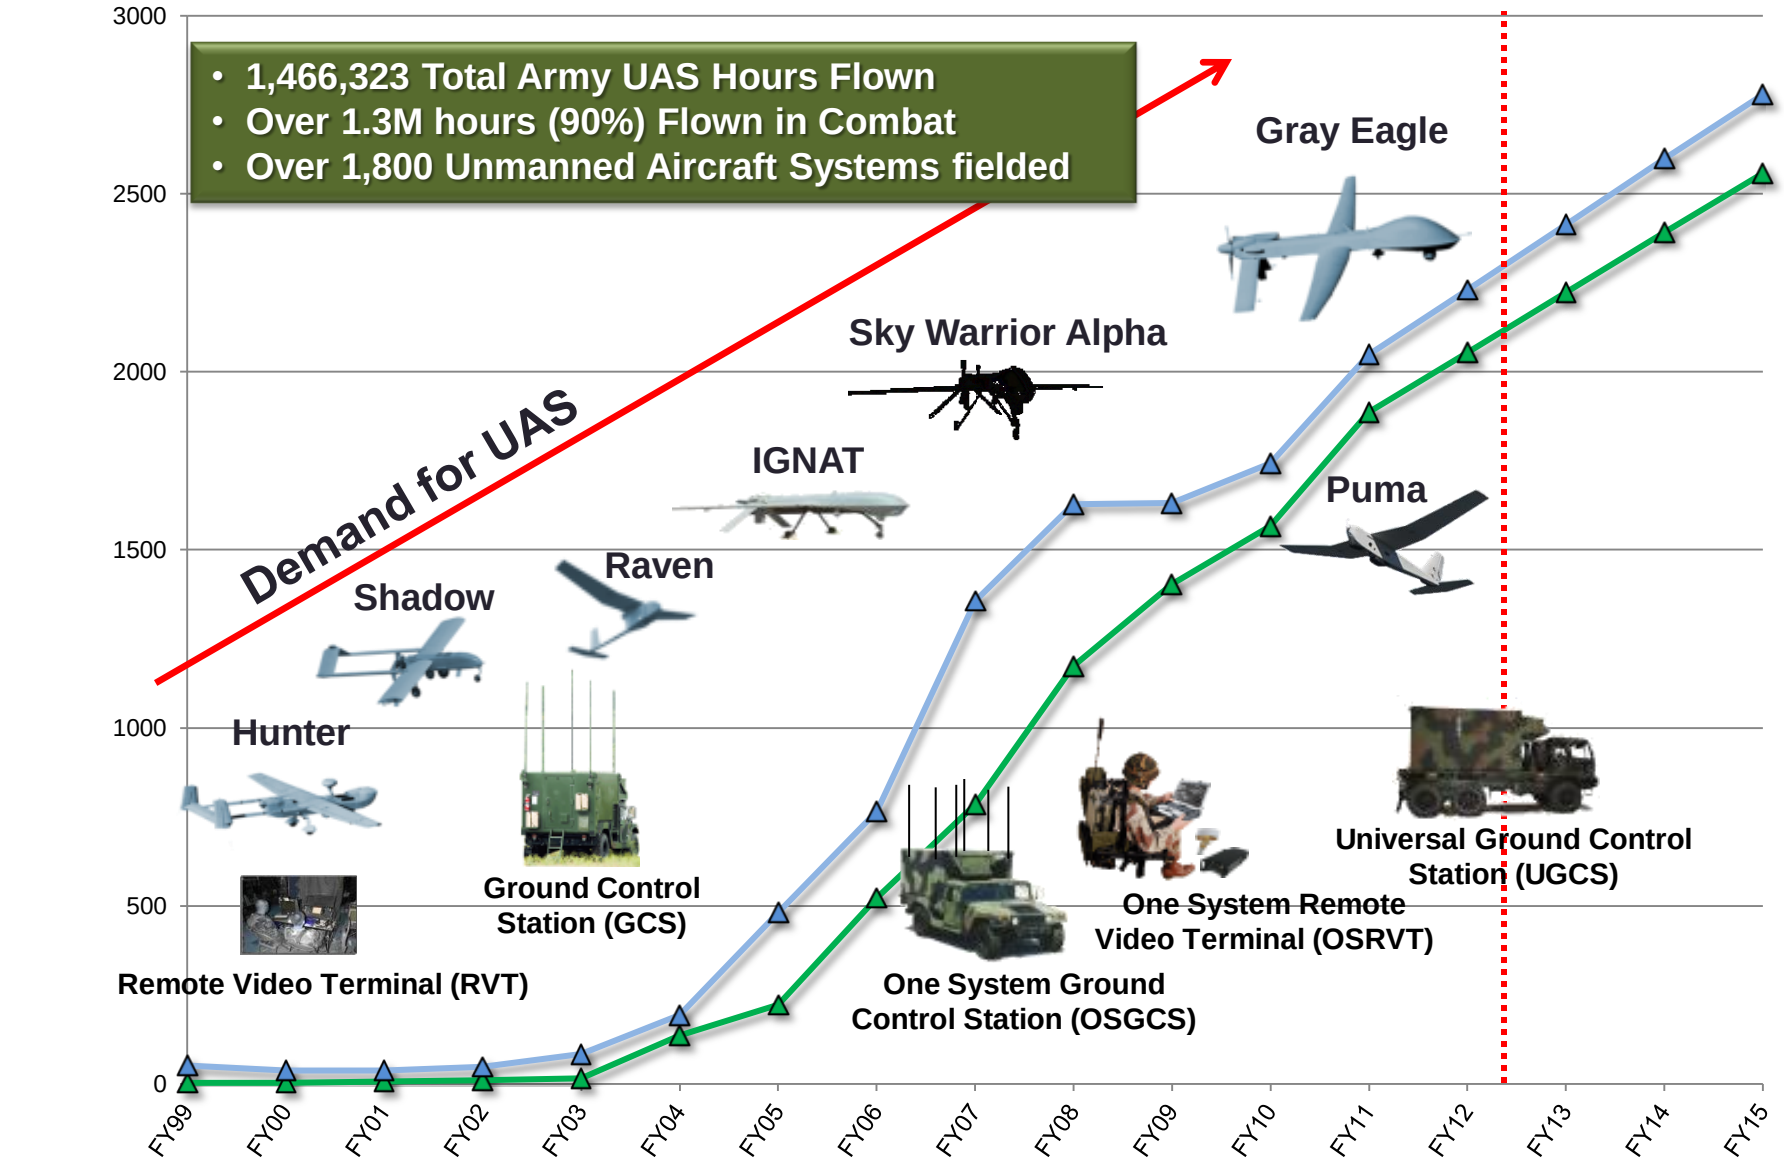
Gray Eagle
MQ-1C

Shadow
RQ-7B

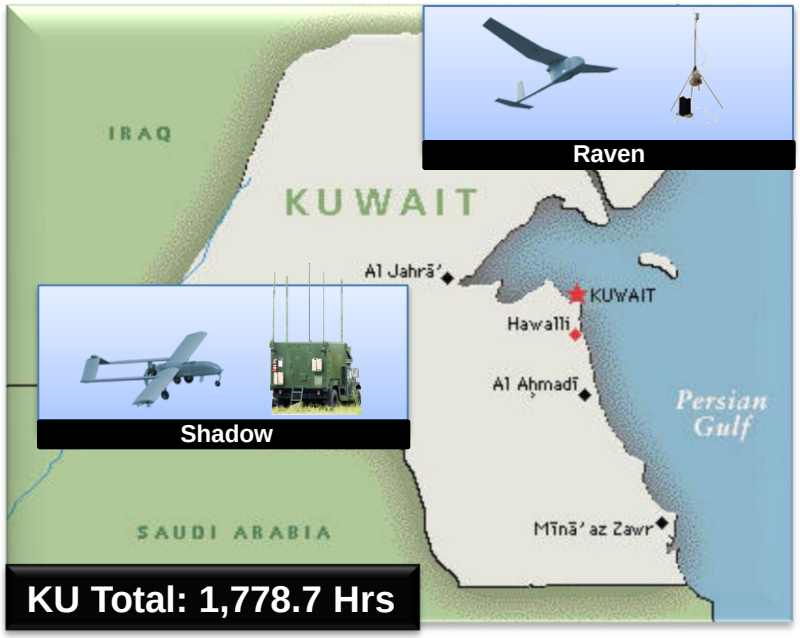
Raven RQ-11B

Puma RQ-20A

Universal Ground Control Station



One System Remote Video Terminal



Army UAS Demand

- 1,466,323 Total Army UAS Hours Flown
- Over 1.3M hours (90%) Flown in Combat
- Over 1,800 Unmanned Aircraft Systems fielded

Aircraft Transport

Hand Controller

GCS & RVT with Battery and Case

EO Sensors

EO/IR/LI Gimbaled Payloads

RSTA Kit

Field Repair Kit

Characteristics/Description

Wing Span	4.6 ft
Air Vehicle Weight	4.4 lbs
Range	10+ km
Airspeed	27-60 mph
Altitude	>300 AGL
Endurance	90 min Lithium
Data Link	Digital Data Link; AES-128 encryption
Payload	Current fixed sensors: • Electro-optical day camera (side and front: 2592x1944 pixels); 3X Zoom; 5 Megapixel • IR (320x240) with Laser Illuminator (25 ft IR spot marking capability) Combined EO/IR/LI gimbaled sensors: • Electro-optical day camera (5MP-2592x1944 pixels); IR (640 x 480); Laser Illuminator
GCS	- 14 lbs (with RSTA laptop)

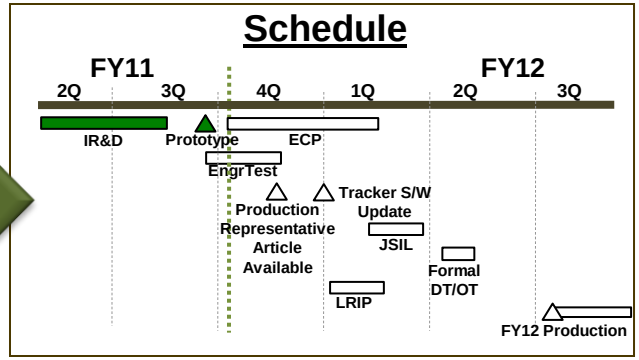
Purpose

Provides the small unit with an increased situational awareness and force protection by providing expanded reconnaissance and surveillance coverage of maneuver areas.

Characteristics

- Rapidly deployed/hand-launched
- SAASM GPS
- Semi-autonomous operations and tele-operations
- In-flight re-tasking
- Commanded auto-loiter at sensor point of interest
- Executes lost link recovery procedures
- Flight termination to pre-planned point
- Decentralized planning and execution
- Common mission planning (AMPS/Falcon View)

Status



- RQ-11B; ACAT III POR – MDA is MG Crosby
- Production buyout of 2358 systems (FY15)
- Raven Surge on schedule
- Gimbaled Payload production begins 3QFY12
- All DDL retrofit kits procured
- Working CPD actions with TCM

RAVEN Gimbaled Payload

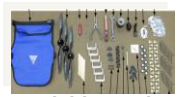
- Response to user requests
- Fits standard DDL Raven with S/W upgrade
- Full gimbal; stow on landing; ruggedized for nose impact
- Sized to accommodate other camera options such as SWIR
- Combined EO/IR/LI Sensors
  - 5MP EO (Same as Puma)
  - 640 x 480 IR (Same as Puma)
  - Laser Illuminator (Same as Raven)
- 3Q FY11 prototyping
- 3Q FY12 production

- Prototypes undergoing flight and qualification testing
- Low rate production planned Fall 2011
- Priority to OEF units

Latest Technology into the Fight

System Overview: RQ-20A Puma AECV

InfiniSpin Payload (3 each)



AECV Aircraft (3 each)

GCS & RVT with Battery and Case
(Same as Raven)

Field Repair Kit

RSTA Kit

Additionally:
- Cables
- Batteries
- Chargers

Characteristics/Description

Wing Span	9.16 ft
Air Vehicle Weight	12.9 lbs (with payload)
Range	10KM (Omni); 20KM (Patch Antenna)
Airspeed	23-41 mph
Altitude	>500 AGL
Endurance	120 minutes
Data Link	Digital Data Link; AES-128 encryption
Payload	- InfiniSpin (Dual mounted/fully gimbaled) - Electro-optical day camera (side and front: 2592x1944 pixels); 3X Zoom; 5 Megapixel - IR (640 x 480) with Laser Illuminator (25 ft IR spot marking capability)
GCS	- 14 lbs (with RSTA laptop)

Purpose

Provides the small unit with an increased situational awareness and force protection by providing expanded reconnaissance and surveillance coverage of maneuver areas.

Characteristics

- Rapidly deployed/hand-launched
- SAASM GPS
- Combined EO/IR/LI fully gimbaled payload
- Target tracking
- Follow-me mode for mobile operations
- In-flight re-tasking
- Executes lost link recovery procedures
- Flight termination to pre-planned point
- Common mission planning (AMPS/Falcon View)

Status

- Non-POR
- Procured under 2 JUONS—288 total systems (includes systems inherited from REF)
- Uses same controller as Raven
- All systems for theater use and training

Spectrum

J/F-12 09670 (check HNSWDO)

- **M1- 1625-1725 MHz DDVL 4M68G7W or 1M56G7W**
- **M2- 1755-1850 MHz DDVL 30 FPS or 15 FPS**

J/F-12 07160

- **216-216.1 MHz Falcon Tracking/Recovery system 10K0P0N**

J/F-12-TBD

- **1090 MHz TICK—No interrogation-periodic transmit**

Spectrum Reallocation

Losing the Lower 25 MHz of the band

- **RAVEN—PUMA– WASP--ACTS**
  - **Can we find a way to compress operations in 5 years, prior to relocating to 2025-2110 MHz in 10 years?**
  - **If asked to vacate the lower 25 MHz indefinitely:**
    - **Can operations be compressed into the upper 70 MHz?**
- **Other 1755 – 1850 MHz Band systems**
  - **Can the other system operations be compressed?**
  - **What combinations of compressed operations can coexist in the upper 70 MHz indefinitely?**
  - **What combinations of compression and relocation are necessary to vacate the lower 25 MHz?**

Spectrum Reallocation Issues

Primary concerns: Deconfliction

Small Unmanned Aircraft Systems vs. Air Combat Telemetry Systems

SUAS- 2 Watts	**vs.**	**ACTS 100 Watts**
SUAS- 25 km normal radius	**vs.**	**ACTS 200 km normal radius**

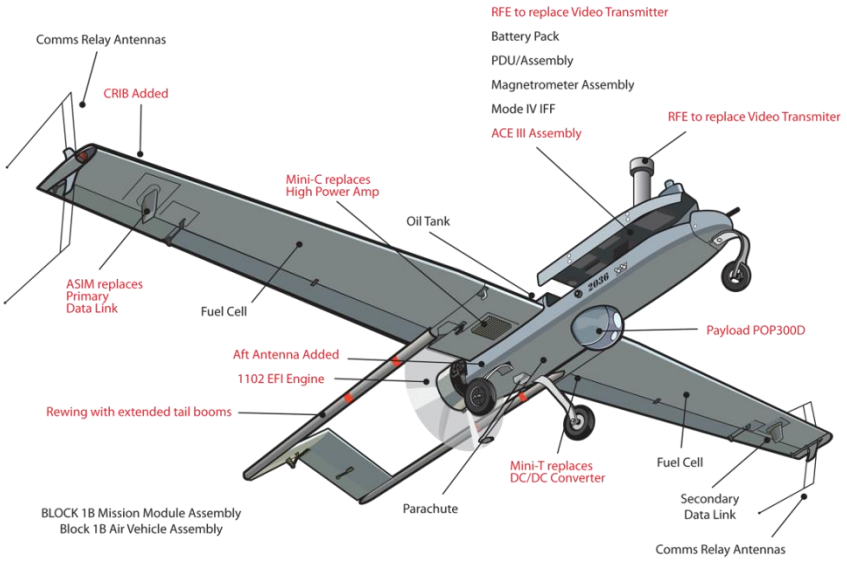
Primary Concerns: Operational

Small Unmanned Aircraft Systems- normally 10 channels for close use

IF we lose the lower 25 MHz:

1) **loss of 3 usable channels**
2) **loss of more channels due to other systems who have to share spectrum, ie; National Training Center's GSM system**
3) **Operational Impact: UNKNOWN- Mission Dependant**

UNCLASSIFIED



Spectrum Reallocation: When?

- **<u>Spectrum Re-allocation for M1755-M1850 Status</u>**

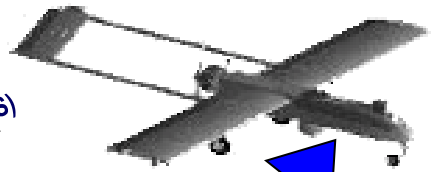
  Commerce Department officials said they wouldn't make a formal recommendation to the FCC about auctioning the airwaves to wireless carriers until government and industry users reach some sort of agreement on how to share the airwaves.

  (as of 3/30/2012)

System Overview: RQ-7B Shadow®

Capabilities

- System consists of **four Air Vehicles, two Ground Control Stations, one rail launcher, and 8 HMMWVs**
- **9 hour endurance**
- EO/IR Laser Designator Payload (**Full Motion Video**)
- Capable of launch and land in remote locations ("soccer field")
- SINCGARS Communications Relay
- 38 HP, 38 pound engine
- 18,000 ft MSL ceiling (supports operations in **Afghanistan** Mountains)
- Type 1 **Encryption** - Tactical Common Data Link



Quantity/Cost

- **Manufacturer: AAI Corporation,** Hunt Valley, MD
- **ACAT II** Program that is now conducting sustainment/upgrades
- **APO: 102** (All systems have been procured; currently fielding system 98)
- **AAO: 115;** There is one Shadow Platoon per BCT, and one in 8 Special Forces Groups; BfSBs and Fires Brigades are not resourced

Differences of Legacy & TCDL

Legacy (or pre-TCDL) Shadow

- Redundant C2 links, 52 bytes @16 Hz
  - Primary link = 2.40 to 2.48 GHz
  - Secondary Link = 340 to 400 MHz
- Video, ~ Analog RS-170
  - CONUS = 4.90 to 4.95 GHz
  - OCONUS = 5.25 to 5.85 GHz

TCDL

- Combines primary C2 & payload into one link
- Ku Band
  - 10.7 Mbps waveform (10.5 down, .2 up)
  - BE CDL (4.0 Mbps, 4.0 down, .5 up)
  - 2.0 Mbps (2.0 down, .2 up)
- Keeps UHF secondary link

System Overview: MQ-5B Hunter

Mission

Unmanned Aircraft System providing 24/7 SIGINT, Intelligence, Surveillance and Reconnaissance to the three Aerial Exploitation Battalions (AEB). Command and Control Via OSGCS and C-Band or TCDL.

History/Present

- **Only UAS fielded at the AEBs (CORPS level).**
- **Peacetime Operations Based OMA**
  - **4 systems fielded (1st MI, 224th, A15th MI, UASTB)**
  - **MTOE of 5 aircraft, Soldiers and 5 embedded CLS**
  - **Interoperability**
  - **Peacetime sustainment to include Depot, supply support, storage, engineering, spares, CLS, CM, Product Assurance and Program Management**
- **Valid Requirement – Directed Requirement**
- **Current direction is to keep Hunter operational until 2022**

Characteristics/Description

Wing Span	34.25 Ft
Max GTOW	1950 Lbs
Range	200Km LOS
Airspeed	62kts cruise/ 110 kts dash
Altitude	18,000 Ft DA
Operational Endurance	20 Hours payload dependent
Weapon	Equipped with Hardpoints
Launch/Recovery	Unapproved runway 1600 ft
Propulsion	HFE

Fleet Status

- **14 supporting OEF**

UNCLASSIFIED

System Overview: MQ-1C Gray Eagle

Mission: Provides the Division Commander a responsive, agile, and flexible capability to perform RSTA, Communications Relay, Manned-Unmanned Teaming and Target Attack Capability

Characteristics/Description

Wing Span	56 Ft 3 in
Max GTOW	3,600 lbs
Range with Relay/SATCOM	>500/1200 km
Max Airspeed	150 kts
Altitude	>25,000 Ft
Endurance	Up to 24 hours
Weapon	Up to 4 HELLFIRE Missiles
Runway (Improved Surface)	4,500 ft max length required

Mission Requirements

- Deployed and integrated with the Combat Aviation Brigade (CAB)
- Immediately responsive RSTA to the Division Commander
- Two simultaneous payloads (EO/IR, Laser Designator, SAR, Communications Relay) and weapons
- "Always on" Medium Communications Relay (SINCGARS, ELPRS)
- Tactical Common Data Link (TCDL) & SATCOM Communications
- Heavy Fuel Engine

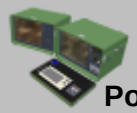
Company Set of Equipment

- 12 Multi-Purpose Aircraft (6 w/SATCOM)
- 6 Ground Control Stations
- 3 Portable Ground Control Stations
- 6 Tactical Common Data Link (TCDL) Ground Data Terminals
- 2 TCDL Portable Ground Data Terminals
- 3 Ground SATCOM system
- 6 Automatic Takeoff and Landing Systems
- Payloads
  - Electro Optic/Infrared (EO/IR)
  - Synthetic Aperture Radar's (SAR) / Ground Moving Target Indicator (GMTI)
  - SIGINT
  - WIN-T Communications Payload (WCP)
- Ground Support Equipment

Gray Eagle System Characteristics

Company Equip Set

(3 Balanced Platoons)



12 Unmanned Aircraft

6 Control Stations

3 SATCOM GDT

6 TALS

Transition plan to Ka SATCOM

Datalinks SATCOM & TCDL

- Ku Band SATCOM with migration to Ka Band NLT FY13
- Increased LOS datalink range over legacy C-band
- Increased bandwidth: TCDL 274 mbs/SATCOM 50 mbs

30" SATCOM

TCDL Antennas

Transition plan to JTRS

Standard Equipment Package

Comms Relay Package-Medium

- Single Channel Comms Relay
- Secure Digital Communications

SINCGARS (x2)

APX-118 IFF

ARC-231

Additional Capabilities

- Airframe
  - 3,600 lb GTOW with 2.0l engine
  - Designed for take-off and landing distance of 4,500 feet
- Near all weather capability
  - Wing De-icing capability allows flight through light icing conditions
  - 20 knot crosswind landing capability
- Redundant Avionics
  - Redundant flight controls
  - Triple-Redundant flight processors
  - Redundant I/O & Power Bus
- Dual Automatic Take-off & Landing (ATLS)
  - Differential GPS
  - Back-up TALS (same as Shadow UAS system)
- Multiple hard points for weapons and external stores
  - (4 x on wings, 1 x center lower fuselage)
- Multiple Payload Bays
  - (2 x Forward Bays, 1 x Aft Bay)

Transition plan for WIN-T & SIGINT

Payloads

EO/IR/LD

SAR/GMTI

SIGINT

HD/TLA

WIN-T/JTRS

HELLFIRE Missiles

- Up to 4 HELLFIRE Missiles
- Current: HELLFIRE II UAS Variant Missiles
- Future: Transition to AGM-114R & JAGM

Heavy Fuel Engine

- Diesel JP-8
- Reduced logistics due to common fuel
- 2.0 l Engine Provides:
  - Increased climb rates
  - Faster dash speeds
  - Increased fuel efficiency

The System is much more than just an Aircraft

UNCLASSIFIED

Ground Based Sense and Avoid System Description

Mission

Ground Based Sense and Avoid (GBSAA) will provide Unmanned Aircraft Systems (UAS) with the capability to "see and avoid" other aircraft in the National Airspace System. GBSAA eliminates the need for visual observers and provides the ability to test and train at night.

History/Present

- First historic night flights in the NAS with a Sense and Avoid system occurred the week of 27 April 2011 at El Mirage, CA (ELMO) with Army GBSAA/Gray Eagle.
- Army has transitioned test activities from ELMO to Dugway Proving Ground to facilitate accelerated fielding schedules
  - Testing in restricted airspace (no FAA oversight necessary).
  - Testbed currently operates with existing radar systems (Range/ATC) with plans to install two 3D radar in Spring 2012
- As OSD Task Force GBSAA Lead, working with the tri-services to develop Common GBSAA requirements that support cost leveraging and mission needs for all

GBSAA System Description

Key Building Blocks

- Commonality
- Interoperability
- Expandability
- Safety/ System Confidence
- Early Capability (Now)
- Baseline System (prototypes)

- GBSAA provides the necessary intelligence to the UAS to mitigate or provide an alternate means of compliance to the FAA "see and avoid" regulations (FAR Part 91.113)
- GBSAA system includes all available sensor data, correlation, fusion, communications, networks, logic, procedures and user interfaces

Path Forward

- Army continues to serve as GBSAA lead developer , as designated by the OSD UAS Task Force, with the following goals:
  - Interoperability across services and platforms
  - Expeditious NAS access with easy capability growth
- GBSAA has received POM funding in FY 13-15 to support fielding to five Gray Eagle sites.
- Interoperability and Technology demos utilizing the DPG testbed currently planned for Summer 2012
  - Live/Virtual/Distributed tests demonstrating interoperability of system components to support Common GBSAA requirements development among the tri-services

GBSAA Frequency Usage

- **Radar is AN/TPQ-50(modified) but still fits into same 1494 specifications**
- **J/F-12 09652 1215-1390 MHz**

  4M80Q3N & 2M77Q3N PEP: 2560 W
- **Assignments at Dugway Proving Grounds- 2 Systems**
- **Working site locations and frequencies for all Gray Eagle fielding sites. Fort Hood, Stewart, Bragg, Campbell, & Riley**
- **Possible conflicts: fielding of AN/TPQ-50 to tactical units on same installation.**

Issues

- **IFF- Aims Certification Testing-seems to be constant changes in procedure to obtain assignment**
- **Last Minute requirements from Higher Headquarters**
- **Requestors not realizing lead times for assignment**
- **Contingency discussions overseas lead to “need now” reactions by leadership**
- **Obtaining “official” DD-1494 approval for devices**
- **Quantities of systems to operate simultaneously**
- **More than one PM working on same platform at the same location(ie: A-160)- confusing when AFMO gets multiple requests**

Summary

The U.S. Department of Defense (DoD) faces a tightening budget in the coming years. Despite the lean budget years, unmanned aircraft systems (UAS) are expected to be a priority. Secretary of Defense Leon Panetta has pledged to maintain or even increase spending in critical mission areas, such as cyber offense and defense, special operations forces, and UAS (Shanker and Bumiller 2011). Due to their usefulness for intelligence collection in irregular warfare (IW) and counterinsurgency (COIN), UAS were quickly fielded and sent to theater without analysis of how their intelligence sensors complemented each other (Isherwood 2011). There are ways for DoD to improve the methods of employment and the integration of multi-intelligence capabilities on assets to better leverage the systems it currently owns.

The general aim of this research is to identify and explore an area in which DoD can operate "smarter" with its proliferating UAS fleet by leveraging geolocation. Geolocation is the identification of the physical location of an object. Specifically, this research investigates how DoD can better leverage UAS and improve multi-intelligence capabilities by expanding its geolocation capacity through the use of time/frequency-difference-of-arrival (T/FDOA) geolocation on UAS.

I focused on the geolocation of radio frequency (RF) emitters used in a military context. There are several different techniques to geolocate an emitter. This research investigates the use of T/FDOA geolocation on UAS and sheds light on important questions that need to be answered before investing in a T/FDOA capability for UAS.

To perform this research, I created a tool to estimate the accuracy of T/FDOA geolocation to quantify its effectiveness. The T/FDOA Accuracy Estimation Model takes a scenario for geolocation and estimates the accuracy of the cooperative T/FDOA technique, including the impact of various sources of errors. Quantifying the effectiveness of T/FDOA geolocation allows this research to answer the proposed research questions. Beyond the analysis in this dissertation, the tool

3061 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

would be useful for assessing the dominant factors in T/FDOA geolocation accuracy, which can inform decisions on choosing aircraft orbit geometries to optimize performance, technology investment decisions, and comparisons of the performance of T/FDOA with alternative geolocation techniques for specific applications.

I first demonstrate the potential of T/FDOA geolocation in the context of how we use UAS today to show what a signals intelligence (SIGINT) system capable of T/FDOA would add. I contrast the T/FDOA technique with direction finding, which is the common geolocation technique used in the military today. T/FDOA geolocation is useful against many targets, particularly those in an IW/COIN environment that are difficult to geolocate using direction finding. Two of the major drawbacks to T/FDOA are the need for multiple platforms and the sensitivity to geometry. The drawbacks do not hinder employment of T/FDOA as a secondary capability on UAS.

I then show some of the requirements of adding a T/FDOA geolocation capability to UAS. Small changes are necessary to implement T/FDOA on UAS. The technology for T/FDOA-capable sensors already exists, and many UAS are nearly equipped to be capable. Today, one of the largest drivers of manpower for UAS is the processing, exploitation, and dissemination (PED) needed to turn the data collected into actionable intelligence. The manpower and cost implications appear to be small compared with the requirements to PED other sensors.

Finally, I explore how T/FDOA geolocation could improve multi-intelligence operations. Adding a SIGINT with T/FDOA capability to UAS instantly increases our ability to provide more information about targets by layering complementing intelligence, surveillance, and reconnaissance (ISR) sensors. T/FDOA geolocation provides high-accuracy geolocation very quickly, reducing the time delay between intelligence types and the area that a second intelligence, such as full-motion video (FMV), would need to search. For command, control, and communication (C3), the emerging ISR mission type orders (MTO) concept meets the C3 needs for T/FDOA geolocation in complex operating environments.

1. Introduction

Problem Statement

The U.S. Department of Defense (DoD) faces steep budget declines over the next decade. Military acquisition and research, development, test, and evaluation will likely be the hardest hit by spending cuts (Eaglen and Nguyen 2011). Despite the lean budget years, unmanned aircraft systems (UAS) are expected to be a priority. Secretary of Defense Leon Panetta has pledged to keep the spending constant or even increase spending in critical mission areas, such as cyber offense and defense, special operations forces, and UAS (Shanker and Bumiller 2011). As part of the plus-up to fight the wars in Afghanistan and Iraq, DoD invested heavily in UAS for intelligence, surveillance, and reconnaissance (ISR). The result was quickly fielding and sending to theater complex systems. The UAS inventory surged from 163 in February 2003 to over 6,000 today (Bone and Bolkcom 2003; Kempinski 2011). These UAS were rapidly amassed and employed, with very little analysis of how the different ISR sensors complemented each other (Isherwood 2011). There are ways for DoD to improve the methods used to employ UAS and the integration of multi-intelligence capabilities on assets to better leverage the systems it currently owns. The general aim of this research is to identify and explore one area in which DoD can operate "smarter" with its proliferating UAS fleet by leveraging geolocation. Geolocation is the identification of the physical location of an object. This research focuses on a method of employment coupled with small technological changes that can significantly improve the geolocation capabilities of DoD.

Specifically, this research investigates how DoD can better leverage UAS and improve multi-intelligence capabilities by expanding its geolocation capacity through the use of time/frequency-difference-of-arrival (T/FDOA) geolocation on unmanned assets. This advancement in geolocation would improve several aspects of ISR. It would increase the hunting ability for UAS, which are often termed hunter-killer platforms, potentially shortening the kill chain. Focusing on ISR,

3074 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

improved geolocation would enable better cross-cueing between platforms or self-cueing on multi-intelligence platforms, creating a richer intelligence picture. Incorporating T/FDOA geolocation would require changes. A new concept of operation (CONOP) needs to be developed for the execution of T/FDOA from ISR platforms and the incorporation of multi-intelligence sources. Payload modifications, though hypothesized to be modest, need to be quantified. The impacts on the processing, exploitation, and dissemination (PED) process also need to be evaluated to determine the efficacy of this concept. This research is intended to inform DoD policy by showing that an expanded use of T/FDOA geolocation on UAS would improve multi-intelligence capabilities.

MOTIVATION AND BACKGROUND

The 2010 Quadrennial Defense Review (QDR) stresses the importance of increased ISR to support the warfighter. The QDR articulates several priorities involving the growth of ISR, including expansions of the "intelligence, analysis, and targeting capacity" and of "unmanned aircraft systems for ISR" (Department of Defense 2010). The *Unmanned Systems Integrated Roadmap FY2009-2034*, published by the Office of the Under Secretary of Defense for Acquisition, Technology, and Logistics, outlines priorities for future investment in unmanned systems and echoes similar themes. The top two priorities for future investments in UAS are improvements in reconnaissance and surveillance, particularly multi-intelligence capable platforms, and improvements in target identification and designation, including the ability to precisely geolocate military targets in real time (Under Secretary of Defense for Acquisition, Technology, and Logistics 2009).

Geolocation is the identification of the physical location of objects on the earth. The term is used to refer to both the action of locating and the results of the localization. There are numerous ways to accomplish geolocation. This research focuses on the geolocation of radio frequency (RF) emitters used in a military context. Geolocation of RF emitters is critical to a wide variety of military applications. In conflicts, geolocation is vital for both targeting and situational awareness. RF emitters of interest range from elements of an integrated

3075 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

air defense system and communications nodes in a major combat operation to insurgents communicating with push-to-talk radios. A key difference in military geolocation is the non-cooperation of targets. An enemy usually attempts to disguise emissions using evasive techniques that complicate geolocation. For example, the time of transmission might not be known. The military uses signals intelligence (SIGINT) to take advantage of the electromagnetic emissions intercepted from targets. These electromagnetic emissions can provide information on the intention, capabilities, or location of adversary forces (AFDD 2-0).

Many intelligence tasks depend on geolocation; however, each task does not require the same level of accuracy. Table 1.1 summarizes specific intelligence tasks requiring geolocation, comments on the value of geolocation, and gives an idea of the accuracy needed. Although these accuracies are intended to be ballpark figures, they highlight the need for significant accuracy for certain tasks, such as precision location.

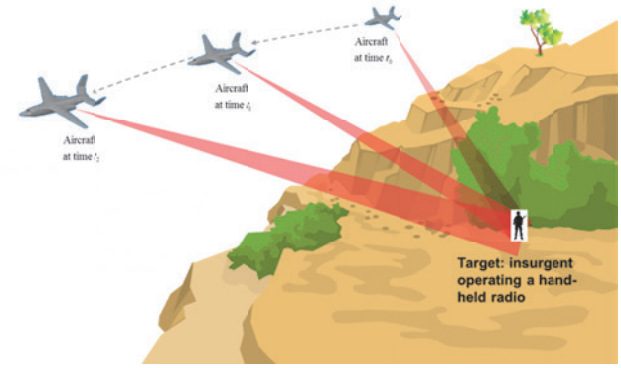
Table 1.1
Geolocation Contribution to Intelligence Tasks

Objective	**Value**	**Accuracy Needed**
Weapon sensor location (self-protection)	Allows threats to be avoided or negated through jamming	Low ($5km^2$)
Emitter differentiation	Allows sorting by location for separation of threats for identification processing	
Enemy asset location	Allows narrowed reconnaissance search	Medium ($1km^2$)
Electronic order of battle	Locate emitter types associated with specific weapons/ units. Provides information on enemy strength, deployment, etc.	
Weapon sensor location	Allows threat to be avoided by other friendly forces	
Precision target location	Allows direct attack	High ($100m^2$)

SOURCE: Table adapted from Adamy, D. (2001). EW 101. Boston, Artech House. p. 144.

3076 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

There are several techniques currently used to geolocate an RF emitter. These techniques include using the angle of arrival (AOA) of the emission, using coherent time-difference-of-arrival (TDOA) at a single platform, using non-coherent TDOA for the emission to multiple receivers, and using the frequency-difference-of-arrival (FDOA) for the emission to multiple receivers. Each of the techniques depends on precise measurements. Errors in the accuracy of the measurements impact the accuracy of geolocation, resulting in some amount of error inherent in the geolocation.



The errors involved and the impact on the accuracy of the geolocation depend on the technique used. These errors include such things as positioning errors (how well the aircraft knows its own position), signal measurement errors (how well the receiver can capture the received signal), and noise inherent in the signal. To reduce error, techniques can be combined and used together, for example T/FDOA geolocation leverages both TDOA and FDOA to determine position more accurately. Regardless of the system used, the geolocation accuracy is dependent on the accuracy of the chosen technique and how the SIGINT system is designed to minimize error (Adamy 2001).

The military traditionally uses direction finding, also known as triangulation, to fix the position of an emitter using specialized manned aircraft. In direction finding, an aircraft would measure the AOA at multiple locations along a baseline to create lines of bearing (LOBs) between the receiver and the emitter. Two or more LOBs enable the emitter to be fixed at the intersection of these different LOBs. Figure 1.1 depicts a pictorial of direction finding. Single-receiver direction finding requires one receiver to measure the signal at one position and then move and re-measure the same signal. Multi-receiver direction finding requires at least two geographically separated receivers collecting LOBs on the same target. There are many algorithms available to calculate the emitter location. These range from plotting LOBs on a common map to calculations based on statistical techniques such as least-squares error estimation and the discrete probability density method (Poisel 2005).

3077 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

There are limitations to direction finding. It requires a directional antenna, which can be bulky and expensive. The accuracy of direction finding can be severely hampered by the duration of the emission as well as target movement. Cooperative T/FDOA geolocation is not subject to these limitations.

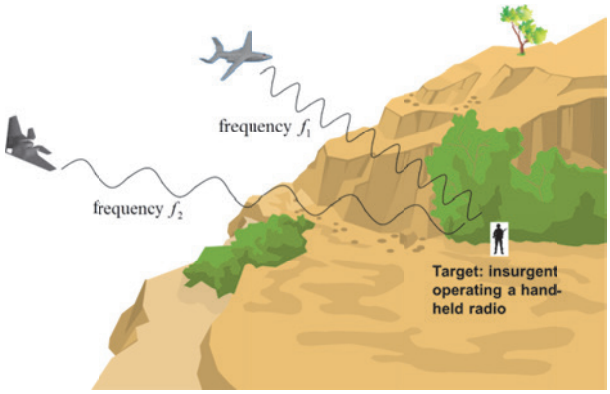


Figure 1.1
Aircraft Calculates LOBs along a Baseline

Cooperative T/FDOA is the combination of two techniques that enable receivers to quickly geolocate a signal. For both TDOA and FDOA, at least two receivers are needed to calculate a difference of arrival. In TDOA, the difference in the time that a signal arrives at the two receivers is proportional to the difference in the ranges of the two receivers from the target. One TDOA measurement provides a contour in the shape of a hyperbola of potential positions of the signal. In FDOA, the difference in the frequency of arrival is proportional to the difference in the frequencies measured by the two receivers. Figure 1.2 shows a pictorial of FDOA. One FDOA measurement provides a contour of potential sources of the signal. When the contours of potential sources of the signal (one from TDOA and one from FDOA) are intersected, the position of the source of the signal is at the intersection.

3078 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 1.2
Signal May Have a Frequency Difference

TDOA and FDOA are straightforward to describe mathematically. The equations for TDOA and FDOA are described by position, velocity, and signal characteristics. Let τ denote a TDOA measurement and ϕ denote a FDOA measurement. Let $v \in \mathbf{R}^n$ and $w \in \mathbf{R}^n$ denote the positions of the pair of receivers in n-space. Similarly, let $\bar{v} \in \mathbf{R}^n$ and $\bar{w} \in \mathbf{R}^n$ denote the corresponding velocities of the pair of receivers. Let c denote the speed of light and f denote the center frequency of the emitter. The equations to calculate TDOA and FDOA are as follows[2]:

TDOA equation: $$\tau = \frac{1}{c}\left(\|v-x\| - \|w-x\|\right)$$

FDOA equation: $$\phi = \frac{f}{c}\left(\bar{v}^T \frac{(v-x)}{\|v-x\|} - \bar{w}^T \frac{(w-x)}{\|w-x\|}\right).$$

Finding the emitter source using T/FDOA is not as easy to describe mathematically, due to errors causing inconsistent measurements of TDOA and FDOA. The T/FDOA Accuracy Estimation Tool, developed as part of this dissertation, simulates the various errors that impact T/FDOA geolocation and predicts the accuracy that could be expected from a T/FDOA geolocation given a specific application. This tool is used throughout the analysis and is explained in detail in Chapter Two.

[2] For more information on TDOA and FDOA equations, see Stewart (1997).

3079 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Direction finding and T/FDOA are difficult to directly compare. The accuracy of each technique is dependent on the specific application, and so it is more useful to contrast the advantages and limitations of each technique. Table 1.2 shows advantages and limitations for direction finding with a single receiver, direction finding with multiple geographically separated receivers, and T/FDOA.

Table 1.2
Summary of Pros and Cons of Geolocation Techniques

	Direction Finding (Single Receiver)	Direction Finding (Multi-Receiver)	T/FDOA
Requires directional antenna	Yes	Yes (on each platform)	No
Signals of interest	Low power, high frequency	Low power, high frequency	Low power, low frequency
Time needed for geolocation	2-3 minutes	Nearly instantaneous	Nearly instantaneous
Requires multiple aircraft	No	Yes	Yes
Sensitive to target movement	Yes	No	No
Sensitive to geometry	No	Yes	Yes

Adding a T/FDOA geolocation capability to UAS would increase both the capacity and capability for geolocation. Today, the number of large UAS owned by the Air Force is on par with the number of manned

3080 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ISR/command and control (C2) platforms. Placing T/FDOA geolocation on these UAS would more than double the number of collectors capable of geolocation.[3] The UAS inventory is also expected to increase in the coming years, potentially bringing the number of group 4/5 UAS to over 500 for the Air Force and Navy alone. Using T/FDOA geolocation would also expand the overall capability for geolocation. Signals that are difficult to geolocate with direction finding for a variety of reasons, such as length of emission, range from collector, and the frequency used, can be located with good accuracy using T/FDOA geolocation. The techniques are contrasted in more depth in Chapter Three.

The expansion of capability and capacity would benefit several aspects of ISR. Higher-accuracy geolocation yields better intelligence. T/FDOA geolocation is able to achieve high enough accuracy to be targetable. Targetable accuracy geolocation determined by a multi-role UAS, such as an armed MQ-9 Reaper, could shorten the sensor-to-shooter timeline. Geolocation is also very useful for cross-cueing. Today, we use UAS predominantly for their FMV sensors. Unfortunately an FMV sensor has a limited field of view, often compared to looking through a soda straw. SIGINT has a much wider field of view, potentially only limited by the line of sight to the radar horizon. A geolocation tip on a known adversary frequency could be used to cue an FMV sensor to identify and perhaps neutralize the target. The increase in geolocation capacity equates to more information about targets that might not have been captured previously. More and better quality geolocation that is catalogued would have impacts on the later phases of PED, such as forensics. Forensics draws together intelligence derived from multiple sources to provide an in-depth analysis. An example of forensics would be an analysis of a roadside bomb explosion. The analysis would pull all available intelligence to try to determine details about the incident, such as when the bomb was placed, when it was detonated, etc. If catalogued, the expanded collection and geolocation from using

[3]As of Jan 2012, the number of manned ISR/C2 assets (U-2, MC-12, E-3B, E-4B, E-8C, RC-135B/S/U/V/WH, EC-130) was 145 aircraft (according to fact sheets on www.af.mil). The number of large (group 4/5) multi-role/ISR UAS is approximately 180 aircraft (according to the Aircraft Procurement Plan FY2012-2041).

3081 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

T/FDOA on UAS could increase the available information for forensic analysis.

T/FDOA Implementation in the Military

For several decades, the military invested in technologies to improve geolocation through the implementation of T/FDOA geolocation, although to date this technology has not been incorporated on UAS. The Precision Location and Strike System (PLSS) was one of the first efforts to use TDOA geolocation. Throughout the 1970s, this program attempted to quickly triangulate hostile emitters with high enough accuracy to target with weapons using a combination of TDOA and other techniques (U.S. Congress Office of Technology Assessment 1987). It utilized three aircraft collecting electronic intelligence data. These data were then relayed to a ground station that used TDOA, direction of arrival, and distance measuring equipment to fix the position of the target. The Air Force spent millions of dollars on the development of PLSS, but the project never succeeded because of technical challenges (Pocock 2008).

The advent of GPS, improvements in computer processing power, and higher-bandwidth communications since the early 1990s enabled more recent attempts to use T/FDOA geolocation for near-real-time precision location of hostile emitters from the air. In 1991, the Army upgraded its Guardrail Common Sensor system to have a limited TDOA capability that depended on an initial cue.[4] In 1997, the Defense Advanced Research Projects Agency (DARPA) began work on Advanced Tactical Targeting Technologies (AT3), the first system designed and built to fully employ T/FDOA geolocation. DARPA's goal was to develop and demonstrate the enabling technologies for a cost-effective, tactical targeting system for the lethal suppression of enemy air defenses. The idea was to generate and distribute highly precise location of radars within seconds using T/FDOA geolocation. Emitter collection packages would be hosted on combat aircraft, obviating the need for any dedicated collection platforms. Instead, collection would be opportunistic, with

[4] Subsequent upgrades to the Guardrail system added a true T/FDOA capability.

3082 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

minimal pre-coordination required. The DARPA system has been incorporated in the F-16 HARM Targeting System, greatly improving the ability of F-16 Block 50s to quickly locate and engage an emitting target (Cote 2010). Another program, Net-Centric Collaborative Targeting (NCCT), greatly expanded the geolocation capabilities of manned ISR assets. Integrated on assets such as the RC-135, RC-130, EC-130, U-2, and EP-3, NCCT allows separate sensors to cooperatively geolocate a target (Anonymous 2008). To date, such technologies are not incorporated on unmanned ISR assets, such as MQ-9 Reapers or MQ-1C Grey Eagles.

Academic research on T/FDOA geolocation centers on methods of estimation and the impact of errors on accuracy. Chestnut (1982) determined relationships between errors in measurement and geolocation accuracy. Bardelli, Haworth, and Smith (1995) found that the Cramér-Rao lower bounds on T/FDOA measurement are typically so small[5] that positioning errors and other measurement errors predominate. Musicki and Koch (2008) devised a method to estimate emitter location accuracy using T/FDOA and compared it with geolocation results from a direction finding approach. Musicki, Kaune, and Koch (2010) proposed a method for recursive tracking of a mobile emitter using T/FDOA. This research expands on academic literature by examining important questions that need to be answered before investing in T/FDOA-capable UAS.

Much of the academic research on geolocation with UAS focuses on using autonomous, often small UAS that cooperate as a swarm (Okello 2006; Marsh, Gossink et al. 2007; Scerri, Glinton et al. 2007; Liang and Liang 2011). These works highlight advantages of small UAS, including their lower cost and higher mobility. Although small UAS have some characteristics that lend themselves to being used for geolocation, larger UAS provide a significant opportunity to leverage T/FDOA geolocation. This research focuses on larger UAS. Group 4/5 UAS, defined as UAS that have a gross weight of larger than 1,320 lbs, show potential for hosting a T/FDOA capability. Some examples of these UAS include the Army's MQ-1C Grey Eagle, the Air Force's MQ-9 Reaper, and

[5] A Cramér-Rao lower bound gives a lower bound on the variance of any unbiased estimator.

3083 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the Navy's MQ-4C BAMS. These UAS have characteristics that make them a logical choice for integrating a T/FDOA geolocation capability. Their large size gives them the payload capacity needed to host multiple sensors. Their long endurance and employment altitude allow for long collection times over significant geographic areas. The large and growing inventory of group 4/5 UAS provides the required ability to mass numbers of equipped platforms over one geographic area.

RESEARCH QUESTIONS

The chapters that follow each focus on one question to inform the overall recommendation of integrating T/FDOA geolocation on UAS platforms to expand the geolocation capacity and increase multi-intelligence capabilities. The analysis leverages mathematical modeling techniques and geospatial analysis to answer the following research questions:

1. When would T/FDOA geolocation be useful on UAS?
2. What is needed to use T/FDOA geolocation on UAS?
3. How can T/FDOA geolocation be leveraged in multi-intelligence operations on UAS?

Each research question is divided into several tasks that help to answer the questions.

The first research question focuses on whether T/FDOA geolocation would be useful if we were to add the capability to UAS operating today. Specifically, I am interested in whether T/FDOA would fill a gap and be a practical capability on UAS. The accuracy of geolocation of a signal is dependent on the method of geolocation used, the characteristics of the scenario, and the signals of interest. Direction finding is a common geolocation technique used today. T/FDOA geolocation offers distinct advantages over direction finding. First, I explore these advantages using a simple model of direction finding to contrast the two techniques. This model is described in Appendix A. Two major drawbacks of T/FDOA geolocation are that it requires multiple equipped platforms and that the geolocation accuracy is extremely sensitive to the geometry of the receiver platforms in relation to the target emitter. Today, multi-intelligence capable platforms are tasked

3084 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

with one intelligence priority (e.g., signals intelligence-prime), and the orbit flown is optimized for that mission. I examine the impact of these orbit geometries on the expected accuracy given different intelligence priorities using the T/FDOA Accuracy Estimation Tool. For T/FDOA geolocation, the multiple equipped platforms must be operating within line of sight of the same target. Using a combination of geospatial analysis and the T/FDOA Accuracy Estimation Tool, I analyze the line of sight coverage overlap and the resulting accuracy available for specific targets in the current operating environment.

Any modification to how a mission is accomplished will have ramifications and cost implications in other areas. The second research question investigates some of these implications. Before T/FDOA is implemented, the requisite hardware and software modifications to platforms need to be determined. I research DARPA's AT3 program as an example of successful T/FDOA geolocation implementation. An addition of T/FDOA capability will likely impact the already manpower constrained processing, exploitation, dissemination (PED) enterprise. I examine the workload for T/FDOA PED. Then, using the current PED operations conducted by the Distributed Common Ground Systems (DCGS) as a baseline, I determine whether the workload requires additional personnel and calculate the total additional personnel burden. As mentioned in the introduction, fiscal constraints faced by DoD will be severe in the coming years. To recommend using T/FDOA in this climate, an understanding of what the potential cost implications for T/FDOA is necessary. I estimate the cost implications of the additional personnel.

Most UAS are equipped with several different types of sensors. DoD would like to capitalize on these multi-intelligence capable platforms to collect more complete information on targets and use one intelligence collection to cue another intelligence collection. The third research question explores how T/FDOA can improve multi-intelligence operations. T/FDOA geolocation can provide highly accurate

3085 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

geolocation within seconds.[6] This combination of accuracy and speed can in turn aid in multi-intelligence collection through improved cueing. The time burden of T/FDOA geolocation is impacted by the command, control, and communication (C3) channels used to pass the geolocation from the analysis source to the warfighter. Today's C3 channels were designed to pass geolocation from manned intelligence platforms, commonly using direction finding, where timeliness is not as important. I examine the kind of C3 needed to enable multi-intelligence cross-cueing.

The research outlined above sheds light on important questions that need to be answered before investing in T/FDOA-capable UAS. The first research question demonstrates the potential of T/FDOA geolocation in the context of how we use UAS today. The second question shows what some of the "costs" of adding a T/FDOA geolocation capability to UAS might be. The third question explores how T/FDOA geolocation could improve multi-intelligence cueing. Each research question helps to inform the overall policy recommendation of better leveraging UAS and improving multi-intelligence capabilities through the use of T/FDOA geolocation.

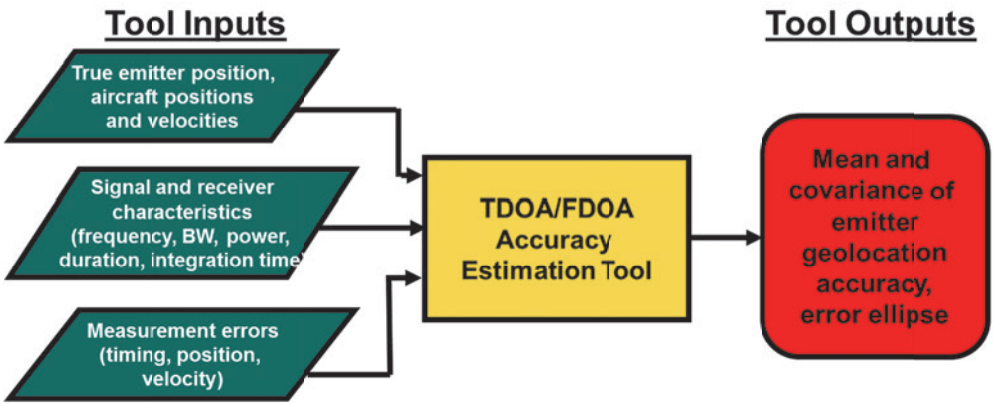
ORGANIZATION OF THE DISSERTATION

Chapter Two presents the T/FDOA Accuracy Estimation Tool that will be used throughout the analysis. Chapter Three discusses when T/FDOA would be useful in the context of today's operations. Chapter Four examines what is needed to use T/FDOA geolocation focusing on the requisite system modifications and the impacts on the PED enterprise. Chapter Five shows how T/FDOA geolocation could be leveraged in multi-intelligence operations. Chapter Six summarizes the conclusions and policy recommendation. Several appendixes are included to provide further information on the models used and results summarized in the body of the dissertation.

[6] An example error ellipse with good geometry would give in a semi-major axis of 37m and a semi-minor axis of 19m, resulting in an area of 2,210m. See Chapter Two for more examples.

3086 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. T/FDOA Accuracy Estimation Model



The T/FDOA Accuracy Estimation Model takes a scenario for geolocation and estimates the accuracy of the cooperative T/FDOA technique, including the impact of various sources of errors. The tool improves on other tools to estimate the accuracy of T/FDOA in the literature by including errors in the measurement of the aircraft state vector. The tool was needed to evaluate the accuracy of T/FDOA as a means of quantifying the benefits of T/FDOA geolocation for this dissertation. Beyond this research, the simulation provides a useful tool for assessing the dominant factors in T/FDOA geolocation accuracy that can inform decisions on choosing aircraft orbit geometries to optimize performance, technology investment decisions, and comparisons of the performance of T/FDOA with alternative geolocation techniques for specific applications.

There are several methods to solve for TDOA and FDOA in the academic literature. Ho and Chan (1993) show how to estimate position at the intersection of two or more hyperbolae using TDOA measurements. Chestnut (1982) derives formulas for cooperative T/FDOA. Ren, Fowler, and Wu (2009) use the Gauss-Newton method for non-linear least-squares to estimate the emitter location using cooperative T/FDOA. Prior work on the estimation of accuracy for cooperative T/FDOA takes into account the precision for the measurement of time difference and frequency difference known as Cramér-Rao lower bounds. Bardelli, Haworth, and Smith (1995) found that the Cramér-Rao lower bounds on TDOA and FDOA are often so small that equipment errors predominate. Equipment errors in the aircraft state vector, such as error in the estimation of position and speed by the platforms conducting the geolocation, have been noted but not explicitly included in previous research. The T/FDOA Accuracy Estimation Model expands on previous research by including measurement errors of the aircraft state vector as well as the traditional Cramér-Rao lower bounds on the measurement of TDOA and FDOA.

3088 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Geolocation using T/FDOA is a complex function of geometry, signal characteristics, and navigational precision. Due to measurement errors and noise, there are limitations on how well an emitter can be geolocated. I use a simulation-based approach to determine the accuracy with which an emitter's position can be geolocated using cooperative T/FDOA. An outline of the inputs and outputs of the T/FDOA Accuracy Estimation Model is show in Figure 2.1.

Figure 2.1
Graphic Depiction of Tool Inputs and Outputs

For each run, I use non-linear least-squares optimization to determine the emitter position most consistent with the simulated measurements. In formulating the least-squares for TDOA and FDOA equations, it is apparent that both functions are not convex, resulting in a non-convex optimization problem. For a non-convex optimization, a good initial estimate is required. I use the true emitter position as an initial estimate to mitigate the possibility of non-convergence.[7] The least-squares fit is also non-linear. I use the Gauss-Newton Method with an approximation of the Hessian for the non-linear least-squares optimization.[8] I then calculate statistics for the distribution of the

[7] The non-convex nature of the problem causes global techniques to fail. Using the true emitter position as the initial estimate guards against non-convergence. The optimization may still fail, and the tool notifies the user of instances of non-convergence.

[8] The Gauss-Newton method is a standard optimization technique for non-linear least-squares optimization. It avoids the direct computation of the Hessian by approximating it, and the approximation improves as

3089 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

estimated positions. I use the sample covariance matrix to determine an error ellipse. The output of the tool is this error ellipse.

MEASUREMENT AND SOURCES OF ERROR

The equations for TDOA and FDOA are described by position, velocity, and signal characteristics. Let τ denote a TDOA measurement and ϕ denote a FDOA measurement. Let $v \in \mathbf{R}^n$ and $w \in \mathbf{R}^n$ denote the positions of the pair of receivers. Similarly, let $\overline{v} \in \mathbf{R}^n$ and $\overline{w} \in \mathbf{R}^n$ denote the corresponding velocities of the pair of receivers. Let c denote the speed of light and f denote the center frequency of the emitter. The equations to calculate TDOA and FDOA are as follows:

TDOA equation: $$\tau = \frac{1}{c}\left(\|v-x\| - \|w-x\|\right)$$

FDOA equation: $$\phi = \frac{f}{c}\left(\overline{v}^T \frac{(v-x)}{\|v-x\|} - \overline{w}^T \frac{(w-x)}{\|w-x\|}\right).$$

As noted in Okello (2006), T/FDOA geolocation requires precise data on the distance between each sensor and a precise clock to synchronize the timing of measurements. Due to measurement errors, TDOA and FDOA measurements are rarely consistent, meaning that an exact solution that satisfies both the TDOA and FDOA equations rarely exists. Our model considers several different sources of error. Consistent with other works, these measurement errors are assumed to be zero-mean Gaussian (Musicki and Koch, 2008). There is error inherent in a receiver's ability to measure its own position and velocity, σ_p and σ_v, respectively. The measurement of TDOA and FDOA each introduce errors due to noise in the receivers, σ_τ and σ_φ. TDOA measurement also includes clock synchronization error, σ_T. The errors and their values are listed in Table 2.1.

---

one approaches convergence. Also, the approximation is always positive definite, which ensures we obtain a descent direction, even for a non-convex problem such as this.

3090 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 2.1
Data for Error Model

Error	Value of Error
σ_p	Default is 10.2 m, based on GPS P(Y) code error
σ_v	Default is 5 cm/s, based on typical error for GPS or low grade IMU
$\sigma_\tau \geq \frac{1}{2\pi B_{rms}\sqrt{BTS_e}}$	I use Cramér-Rao lower bounds (Musicki, Kaune et al. 2010)
$\sigma_\phi \geq \frac{1}{2\pi T_{rms}\sqrt{BTS_e}}$	I use Cramér-Rao lower bounds (Musicki, Kaune et al. 2010)
$\sigma_T = 100\times10^{-9}$ sec	Default is times the worst-case GPS satellite clock error.

PROBLEM FORMULATION

I formulate the problem as a non-linear least-squares optimization problem to find the emitter position that minimizes the deviation from zero for every T/FDOA measurement. I first fit a least-squares optimization to the T/FDOA equations. I want to find the emitter position that is most consistent in the least-squares sense; that is, the emitter position that minimizes the sum of the squared residuals. Let τ_i denote the i^{th} TDOA measurement for $i=1,\cdots,m$. Similarly, let ϕ_i denote the i^{th} FDOA measurement for $i=1,\cdots,m$. Let $v_i \in \mathbf{R}^n$ and $w_i \in \mathbf{R}^n$ denote the positions of the i^{th} unique pair of receivers for $i=1,\cdots,m$. Similarly, let $\overline{v}_i \in \mathbf{R}^n$ and $\overline{w}_i \in \mathbf{R}^n$ denote the corresponding velocities of the i^{th} unique pair of receivers. Let c denote the speed of light and f denote the frequency of the emitter. Then x^* is given by:

$$x^* = \underset{x\in\mathbf{R}^n}{\arg\min} \left\| \begin{matrix} \|v_1 - x\| - \|w_1 - x\| - c\tau_1 \\ \|v_2 - x\| - \|w_2 - x\| - c\tau_2 \\ \vdots \\ \|v_m - x\| - \|w_m - x\| - c\tau_m \\ \overline{v}_1^{\,T}\dfrac{(v_1 - x)}{\|v_1 - x\|} - \overline{w}_1^{\,T}\dfrac{(w_1 - x)}{\|w_1 - x\|} - \dfrac{c}{f}\phi_1 \\ \overline{v}_2^{\,T}\dfrac{(v_2 - x)}{\|v_2 - x\|} - \overline{w}_2^{\,T}\dfrac{(w_2 - x)}{\|w_2 - x\|} - \dfrac{c}{f}\phi_2 \\ \vdots \\ \overline{v}_m^{\,T}\dfrac{(v_m - x)}{\|v_m - x\|} - \overline{w}_m^{\,T}\dfrac{(w_m - x)}{\|w_m - x\|} - \dfrac{c}{f}\phi_m \end{matrix} \right\|^2 .$$

3091 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

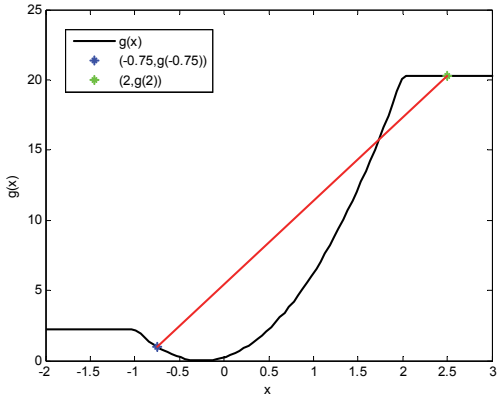
This is a non-convex optimization problem. I can show that a least-squares fit is non-convex through counter examples. If a function were convex, then the entire function would lie on or below a line segment connecting any two points on the function. Mathematically, this is stated as:

$$g(ax+(1-a)y) \le ag(x)+(1-a)g(y), \text{ for any } 0 \le a \le 1 .$$

The function for the normalized TDOA fit would be:

$$g(x)=\left(\|v-x\|-\|w-x\|-c\tau\right)^2 .$$

Let $v=2, w=-1,$ and $c\tau=1.5$. I can then check the convexity for this example by graphing. The graph on the left in Figure 2.2 shows clearly that the least-squares fit to TDOA is not convex. Similarly, the function for the normalized FDOA fit would be:



$$g(x)=\left(\bar{v}^T\frac{(v-x)}{\|v-x\|}-\bar{w}^T\frac{(w-x)}{\|w-x\|}-\frac{c\phi}{f}\right)^2 .$$

If we set the data, let $\bar{w}=\bar{v}=1, v=2, w=-1, and\ c\phi/f=2.5,$ we can graph the function. The graph on the right in Figure 2.2 shows that the least-squares fit to FDOA is also not convex.

Figure 2.2
Graph of TDOA and FDOA for Convexity Proof

Graph of TDOA

Graph of FDOA

As a result of the non-convexity, the algorithm may not converge to a global minimum. If it is provided an initial estimate that is close to optimal, the algorithm will converge in most cases. For our application, we know the true position of the emitter and use it as our initial estimate.[9] This does not guarantee convergence for every case; however, it works in most situations. The tool informs the user if the solution did not converge, and these data are removed for the statistical calculations.[10]

---

[9] The non-convexity of this problem requires a good initial estimate, in the neighborhood of the optimal solution. Using the true position of the emitter provides an initial estimate that should be close for most cases. This initial estimate will not impact the resulting error ellipse, as the algorithm will still converge at the optimal solution.

[10] The non-convergence is a result of the non-convexity of the problem. Unfortunately, it is unavoidable. When a solution does not converge, it typical means that the initial estimate (the true position) was far from the optimal solution. This situation is the result of poor geometry. As a reviewer noted, removing the failures could impact the accuracy results, since they are the worst cases. I conducted some sensitivity analysis to see the extent of non-convergence. The Monte-Carlo simulation uses 500 iterations, and the percentage of non-convergences is typically very small, less than 5 percent. If the proportion of non-convergences reaches greater than 10 percent, the tool will inform the user that there are not enough samples to estimate the accuracy. I never encountered this situation. In general, if there is non-convergence, the geolocation from that particular application is extremely poor. Removing the failures does

3093 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

I reformulate the problem to simplify the notation. Let τ_i denote the i^{th} TDOA measurement for $i = 1, \cdots, m_1$. Similarly, let ϕ_i denote the i^{th} FDOA measurement for $i = 1, \cdots, m_2$. Assume that m_3 unique pairs of receivers collect the measurements. Let $v_i \in \mathbf{R}^n$ and $w_i \in \mathbf{R}^n$ denote the positions of the i^{th} unique pair of receivers for $i = 1, \cdots, m_3$. Similarly, let $\overline{v}_i \in \mathbf{R}^n$ and $\overline{w}_i \in \mathbf{R}^n$ denote the corresponding velocities of the i^{th} unique pair of receivers. Let $T(i) \in [1,2,\cdots,m_3]$ denote the index of the receiver pair that collects τ_i for $i = 1, \cdots, m_1$ and let $F(i) \in [1,2,\cdots,m_3]$ denote the index of the receiver pair that collects ϕ_i for $i = 1, \cdots, m_2$.

$$\text{Let } r_i(x) = \begin{cases} \left\| v_{T(i)} - x \right\| - \left\| w_{T(i)} - x \right\| - \tau_i c & i = 1, \cdots, m_1 \\ \overline{v}_{F(i-m_1)}{}^T \dfrac{\left(v_{F(i-m_1)} - x\right)}{\left\| v_{F(i-m_1)} - x \right\|} - \overline{w}_{F(i-m_1)}{}^T \dfrac{\left(w_{F(i-m_1)} - x\right)}{\left\| w_{F(i-m_1)} - x \right\|} - \phi_i c / f & i = m_1 + 1, m_1 + 2 \cdots, m_1 + m_2 \end{cases}$$

The optimization problem is now:

$$\text{minimize } g(x) = \sum_{i=1}^{m_1+m_2} r_i(x)^2 \quad .$$

This is a non-linear least squares optimization problem, and I use the Gauss-Newton method with a backtracking line search to solve it. The Gauss-Newton method is an algorithm for solving convex non-linear least-squares problems. The method defines a descent direction using the gradient and an approximation of the Hessian denoted H.[11] I use a backtracking line search to determine the step size. The algorithm as applied to our problem is as follows:

---

not impact the results throughout this dissertation. In the remainder of this research, I categorize the error ellipse accuracy into high (<100m^2), medium (<1km^2), low (<5km^2), and unusable. Non-convergence would only appear in applications that result in unusable accuracies.

[11] This estimate of the Hessian converges to the Hessian as the gradient vanishes.

    $t = t/2$
  end
  $x = x + tu$
end

With each run, the estimated position of the emitter is saved. These estimated positions are used to calculate the mean estimated position and a covariance matrix. Using the eigenvalues of the covariance matrix, we can determine the uncertainty in each direction and plot this uncertainty to create an error ellipse.

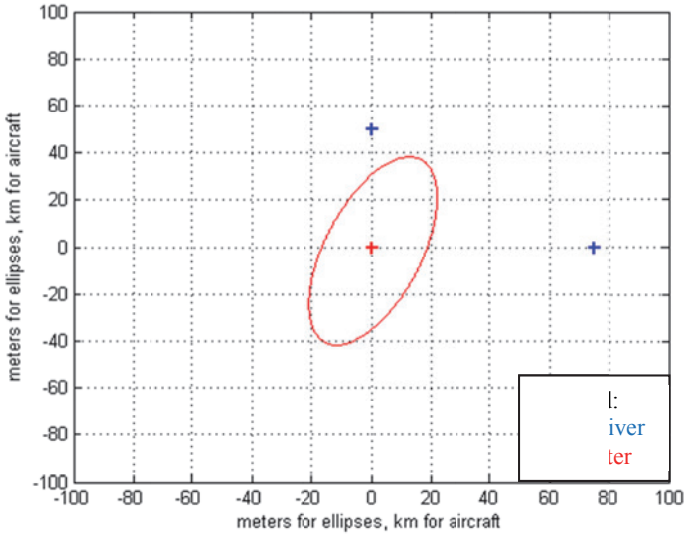
HOW THE TOOL WORKS

The tool uses a Monte-Carlo simulation to estimate the accuracy of geolocation. For each run of the tool, the true TDOA and FDOA are calculated using the true positions. Then, the errors are incorporated. The errors are modeled as separate random samples each drawn from Gaussian distributions with the variance of the error parameter. During each iteration, the randomly sampled error is added to the true value. All of the errors are included in each model run. The errors for TDOA and FDOA measurement (σ_τ and σ_ϕ, respectively) are introduced using the errors from the Cramér-Rao lower bounds. Random synchronization clock error (σ_T) is also added to the TDOA measurement. Then random noise is added to the positions (σ_p) and velocities (σ_v) of the receivers to simulate the aircraft state vector measurement error. For example, if the true aircraft position was [100m, 150m, 90m] and the random error sample for position was 7.8m, the aircraft position used for that iteration would be [107.8m, 157.8m, 97.8m]. The T/FDOA measurement and positions that incorporate the errors are then used in the non-linear least-squares optimization to determine the most consistent emitter

3095 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

position. Statistics between this estimated position and the true emitter position are used as estimates of the geolocation accuracy.

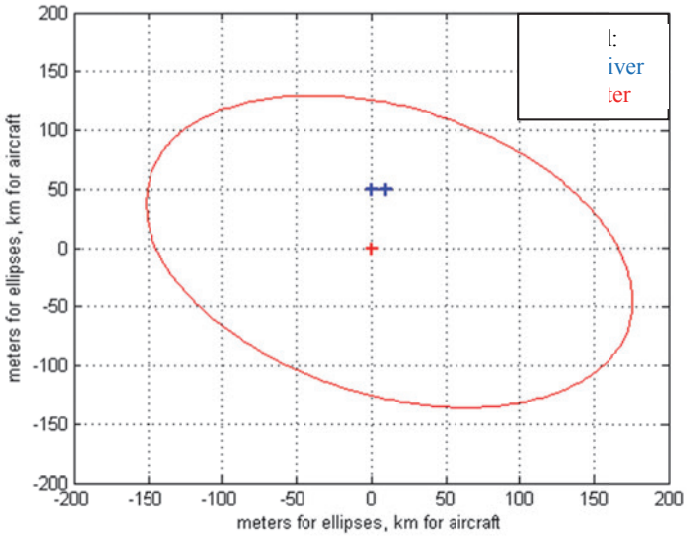
EXAMPLES OF TOOL



The T/FDOA Accuracy Estimation Model shows how the different inputs to cooperative T/FDOA impact the accuracy with which an emitter can be geolocated. The following examples are meant to illustrate the sensitivity of the tool to several of the model inputs. The accuracy is extremely sensitive to geometry and the number of receivers available. By *geometry*, I am referring to the positioning and speed of the receivers relative to the target. The receivers must be located such that there are time differences between the arrivals of the signal. The receivers must also be traveling with different velocities with respect to the targeted emitter so that there are calculable frequency differences of arrivals. The measurement errors can also significantly impact the accuracy of geolocation.

Example: Impact of Geometry

In this scenario, there are two receivers positioned around the emitter. The emitter has a 164 MHz signal that lasts for 30 seconds with a 25 MHz bandwidth, and 5W EIRP, a typical power for a VHF push-to-talk radio. There is a 190°K noise temperature at the receivers with a 4dB noise figure. The receivers are both headed east at 100 m/sec. Figure 2.3 shows the scenario and the resultant error ellipse. The receivers are the blue crosses, and the emitter is the red cross. Positions are in units of kilometers. The error ellipse is in units of meters.

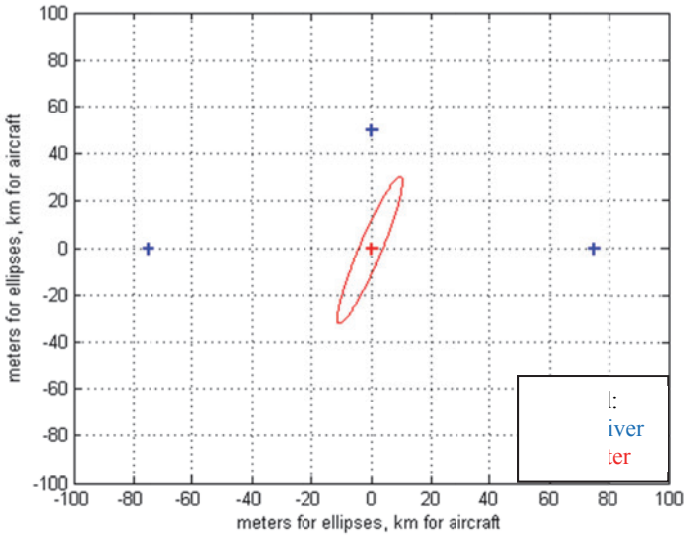


3096 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 2.3
Two Receiver Example with 1-Sigma Error Ellipse

The error ellipse is about 2210m^2 centered on the emitter. If the position of one of the receiver is changed, keeping all else constant, the size of the error ellipse can increase drastically. Figure 2.4 shows the resultant error ellipse after moving one receiver to be much closer to the other.

Figure 2.4
Moving One Receiver for Poor Geometry



3097 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

This new ellipse is about 65,000m^2. As the two receivers move closer together, the difference in arrival for both TDOA and FDOA becomes so small that measurement errors and noise dominant the measurement.

Example: Impact of Number of Receivers

The number of receivers is a major determinant of the size of the error ellipse. Returning to the same scenario as the first example with two receivers positioned advantageously, we can add another receiver.

Figure 2.5
Adding a Receiver

The error ellipse is now much smaller, at 392m^2. The number and positioning of the receivers are significant contributors to the estimated error ellipse.

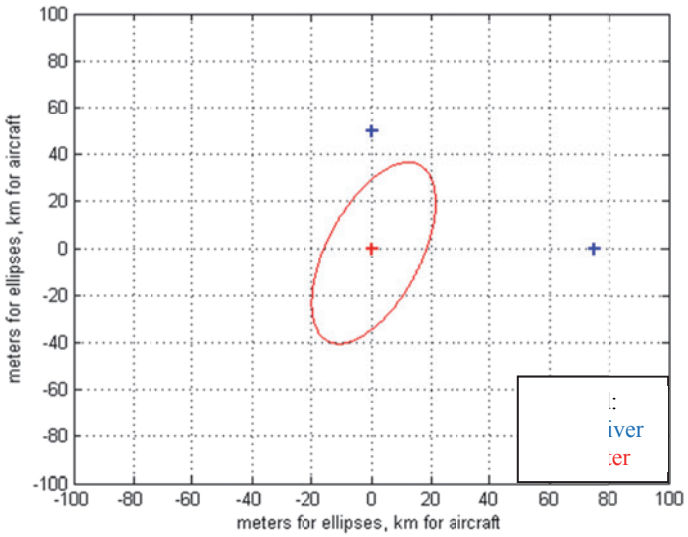
Example: Impact of Measurement Errors

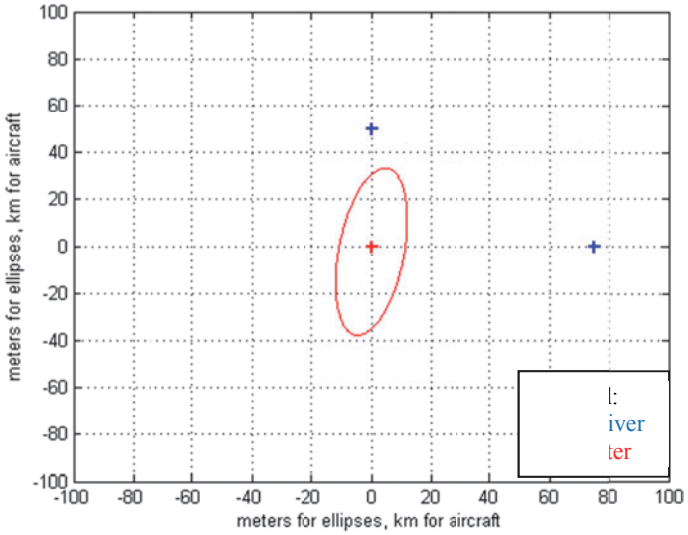
The measurement errors incorporated in the tool are also important contributors to the size of the error ellipse. Again, returning to the same scenario as the first example with two receivers positioned advantageously, we see the impact of the error inherent in a receiver's

3098 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ability to measure its own position and velocity, σ_p^2 and σ_v^2 respectively. These impacts are shown in Figure 2.6 and Figure 2.7.

Figure 2.6
Ellipse with Reduced Position Error





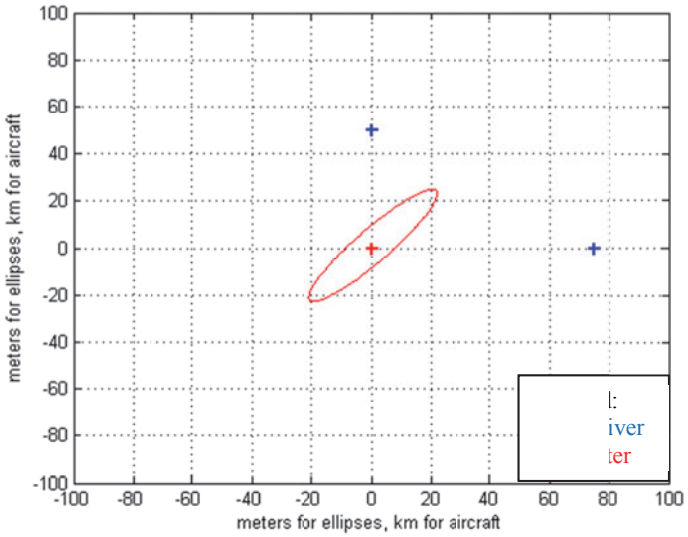


Figure 2.7
Ellipse with Reduced Velocity Error

3099 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Reducing the error in the position measurement by half results in a slight reduction of the error ellipse to 2070m^2. Reducing only the error in velocity measurement by half reduces the error ellipse to 1230m^2.

Figure 2.8
Ellipse with Reduced Time Synchronization Error

Alternatively, decreasing the time synchronization error between the receivers by a factor of 10 reduces the error ellipse to 615m^2. The tool is also capable of handling scenarios in three dimensions. The result is an accuracy ellipsoid that incorporates uncertainty in the estimation of the altitude of the emitter.

The T/FDOA Accuracy Estimation Tool can provide useful information across a variety of applications. The tool can be used to predict the T/FDOA geolocation accuracy given a specific application. It can also be leveraged for research, such as the quantitative analysis in this dissertation. For this research, the tool was needed to evaluate the accuracy of T/FDOA as a means of quantifying the benefits of T/FDOA geolocation.

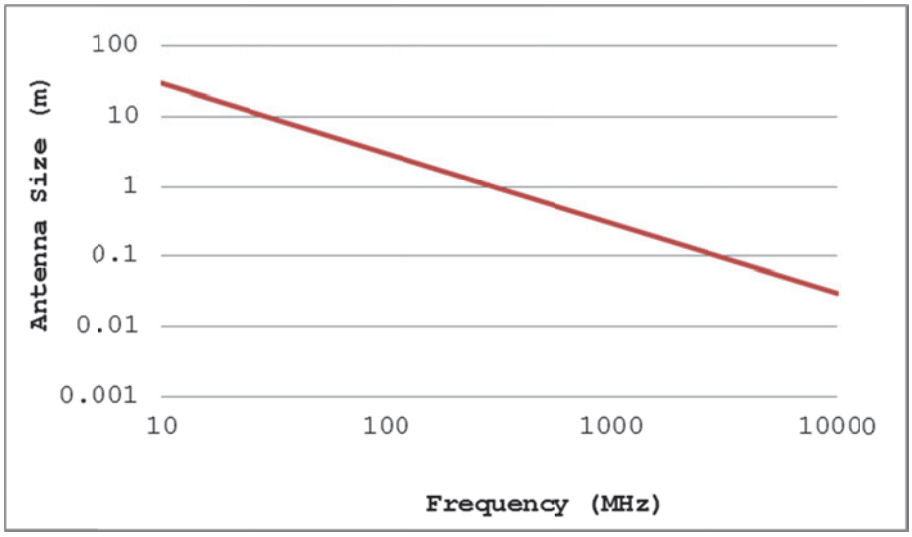
3100 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

3. When Is T/FDOA Geolocation Useful?

This chapter focuses on whether T/FDOA geolocation would be useful as a capability added to UAS operating today. Specifically, I am interested in whether T/FDOA would fill a gap and be a practical capability on UAS. The accuracy of the geolocation of a signal is dependent on the method of geolocation used, the characteristics of the scenario, and the signal of interest. Direction finding is a common geolocation technique; however, T/FDOA geolocation offers distinct advantages over direction finding. I explore these advantages using a simple model of direction finding to contrast the two techniques. The model is described in Appendix A.

Two major shortcomings of T/FDOA geolocation are the sensitivity of geolocation accuracy to the geometry of the receivers and the target and the requirement for multiple equipped platforms. I explore these two drawbacks in the context of today's operating environment. Today, multi-intelligence capable platforms are tasked with one intelligence priority (e.g., full-motion video-prime), and the orbit flown is optimized for that mission. If T/FDOA were to be added to UAS, I assume that UAS would continue performing their primary mission as tasked today, with geolocation done as a secondary mission. I examine the impact of the orbit geometries dictated by the primary intelligence mission on the expected geolocation accuracy using the T/FDOA Accuracy Estimation Tool. For T/FDOA geolocation, the multiple equipped platforms must be operating within line of sight of the same target. Using a combination of geospatial analysis and the T/FDOA Accuracy Estimation Tool, I analyze the line of sight coverage overlap and the resulting accuracy for specific targets in the current operating environment.

A Contrast of Direction Finding and T/FDOA Geolocation



In the Introduction, some advantages and drawbacks to the traditional geolocation technique of direction finding and T/FDOA geolocation were briefly discussed. T/FDOA and direction finding are

3102 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

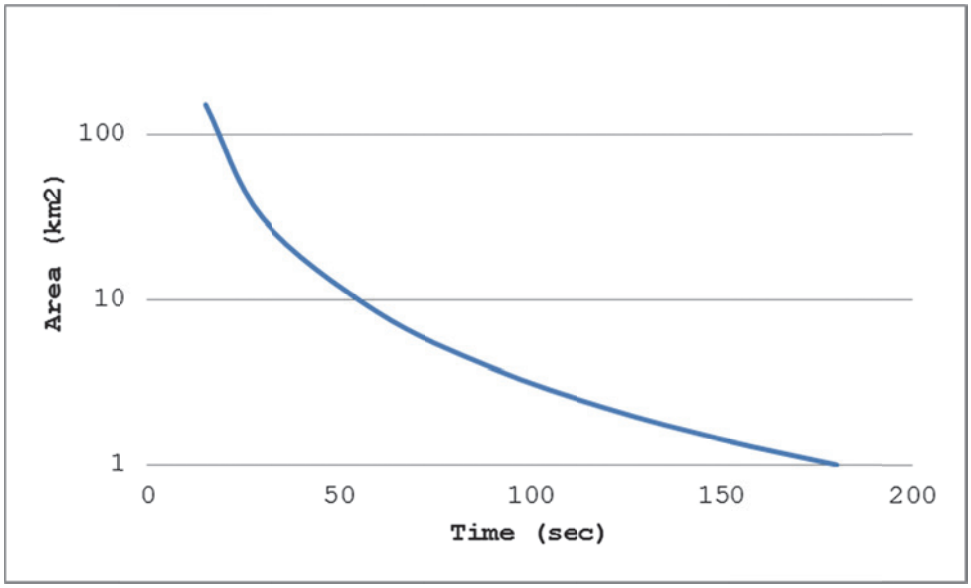
difficult to directly compare, because the accuracy of each technique is sensitive to variables that are specific to each application. It is more useful to contrast the techniques. This section goes into more depth on the advantages of T/FDOA geolocation by contrasting the two techniques. I describe the difference in antenna requirements for each technique and the implication for hosting the antenna on an airborne platform. The accuracy of direction finding is in part dependent on the time that the baseline is flown. I then contrast this time element of each technique. The geometry of the specific application impacts the accuracy of either technique; however, the range between the target and the receiver also influences the accuracy for direction finding.

For a system to use direction finding, it must be equipped with a directional antenna. The capability of a directional antenna to capture signals of different frequencies is directly related to its size. A rule of thumb is that the diameter of a circular antenna must be at least the length of the signal wavelength (Elbert 2008). The minimum circular antenna size required as the signal frequency increases is shown in Figure 3.1.

Figure 3.1
Antenna Size vs Frequency

Tactical communications, such as military push-to-talk radios, often operate in the HF and VHF bands, around 10-300MHz. Attempting to

3103 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



geolocate these types of signals using airborne direction finders can result in unwieldy antennas. For example, locating a 35MHz signal would require an antenna with an approximately 8.6m (~28ft) diameter. To target a 300MHz signal, the edge of the VHF band, requires a directional antenna to have a 1m (3ft) diameter. To put this in perspective, the MQ-1 Predator is only 27ft long, with a 55ft wingspan (ACC Public Affairs 2012). Its much larger counterpart, the MQ-9 Reaper, is 33ft long and has a 66ft wingspan (ACC Public Affairs 2012). Placing a directional antenna capable of receiving VHF band frequencies on a UAS is difficult because of the size, weight, and power (SWAP) limitations inherent with an airborne vehicle. In contrast, T/FDOA geolocation does not require a directional antenna. Instead, a smaller non-directional antenna can be used.[12]

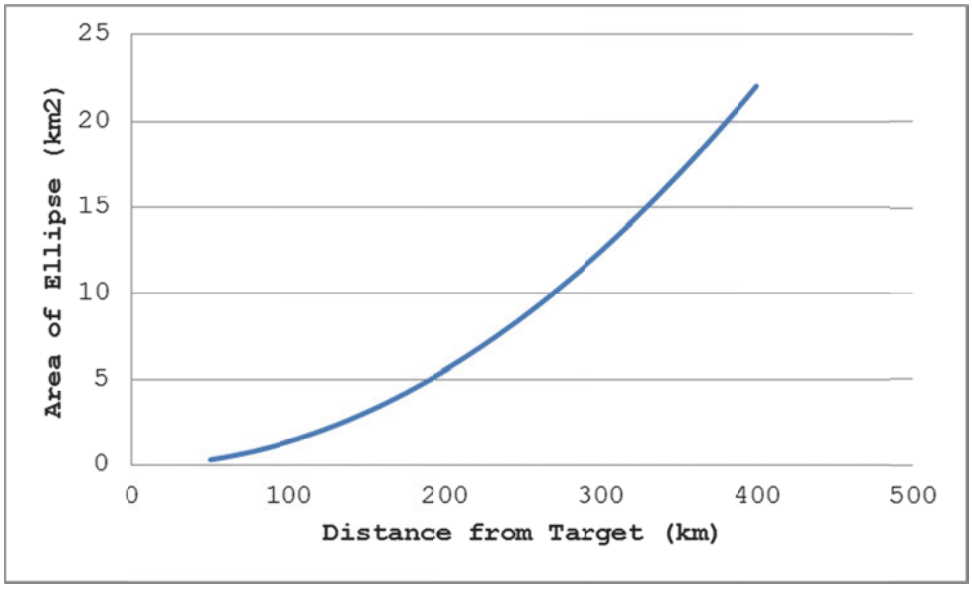
To perform direction finding, an aircraft flies a baseline, measures multiple lines of bearing (LOBs), and then correlates those LOBs to determine the position of the target. The accuracy of direction finding is partly dependent on the length of the baseline, which can be thought of as a length of time. As the length of time a baseline is flown increases, the accuracy of direction finding increases. This relationship is shown in Figure 3.2.

[12] There are additional benefits to a directional antenna. For example, it provides gain, which improves the signal-to-noise ratio. A non-directional antenna does not have that benefit.

3104 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 3.2
Time of Baseline impacts Direction Finding Accuracy

NOTE: Calculations used the DF Model, explained in Appendix A. Assumptions included a range of approximately 125km, an AOA accuracy of 0.08deg, airspeed of 340kts, and a 3sec measurement interval.



In general, accurate direction finding needs a baseline of a few minutes. For a medium accuracy geolocation of 1km^2, a baseline of approximately three minutes would be needed. The accuracy is therefore dependent on a cooperative target that continues to emit throughout the entire baseline. T/FDOA geolocation is not dependent on the length of time of collection. The collection can be extremely short, because the accuracy of T/FDOA geolocation is impacted by the timing synchronization of the correlated signals and not the length of the emission.

The accuracy of direction finding is more dependent than T/FDOA on the range between the receiver and the target emitter. In general, the closer the receiver is to a target, the better the accuracy of geolocation. Since T/FDOA takes advantage of the differences in time and frequency of arrival, T/FDOA does not suffer the same geometric issue related to range as direction finding. For direction finding, the accuracy degrades in a linear fashion with range. This relationship is shown in Figure 3.3. The ratio of the signal strength to noise level,

3105 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the signal-to-noise ratio (SNR), impacts the accuracy for both direction finding and T/FDOA. The greater the range to the target, the lower the SNR and the more degraded the accuracy. In T/FDOA, the SNR is part of the error contribution from the Cramér-Rao lower bounds. Bardelli, Haworth, and Smith (1995) found that the Cramér-Rao lower bounds on T/FDOA measurement are typically very small and not the dominate source of error. Provided there is an adequate SNR such that T/FDOA can be calculated, there is little dependence on range, compared with direction finding.

Figure 3.3
Range to Target Impacts Direction Finding Accuracy

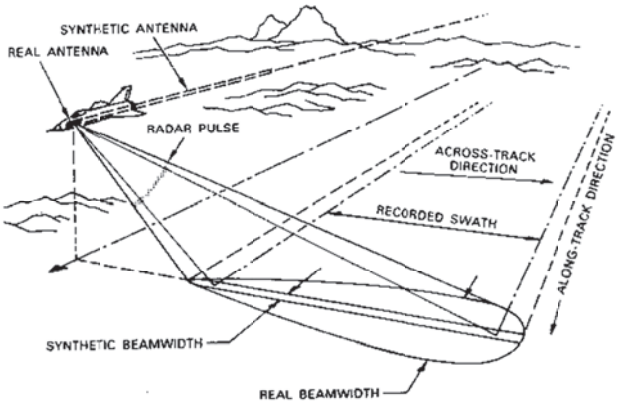
Calculations used the DF Model, explained in Appendix A. Assumptions included a baseline of approximately 120sec, an AOA accuracy of 0.08deg, airspeed of 340kts, and a 3sec measurement interval.

These three advantages—lack of requirement for directional antenna, lack of dependency on emission duration, and lack of dependency on range to target—of T/FDOA geolocation over direction finding make T/FDOA more robust in the types of emitters that can be targeted and less dependent on a cooperative target. A major drawback to T/FDOA is the requirement that multiple platforms receive the same signal and are able to cooperate to geolocate the target. If it were

3106 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

possible to use T/FDOA geolocation in a non-intrusive manner on UAS platforms equipped with other intelligence sensors and continue to achieve highly accurate geolocation, T/FDOA geolocation could greatly expand the geolocation capabilities of the military. The next section investigates the feasibility of using T/FDOA geolocation in a non-intrusive manner on UAS and quantifies the accuracy of geolocation that would be achieved.

Types of Intelligence and Resulting Orbits



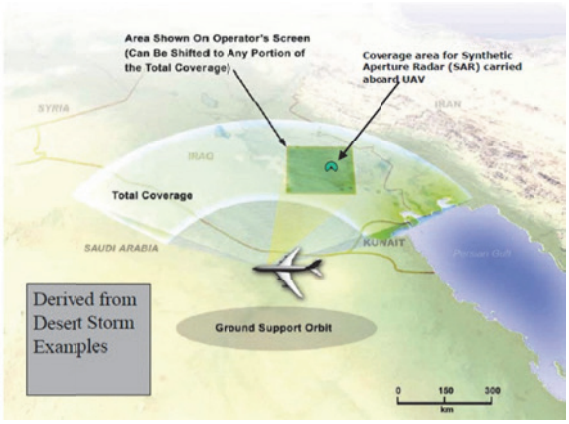
The Air Force categorizes ISR into five intelligence disciplines. These are geospatial intelligence (GEOINT), signals intelligence (SIGINT), measurement and signature intelligence (MASINT), human intelligence (HUMINT), and open-source intelligence (OSINT). Geospatial intelligence is the "exploitation and analysis of imagery and geospatial information to describe, assess, and visually depict physical features and geographically referenced activities on the Earth" (U.S. Air Force 2012). Imagery intelligence (IMINT) is a subcomponent of GEOINT that is defined as images that are recorded and stored (U.S. Air Force 2012). IMINT includes radar, infrared, or multispectral imagery, traditional visual photos, and full-motion video. This analysis focused on the various types of IMINT because those are the types of sensors most often hosted on UAS. The next several paragraphs explain intelligence missions that can be accomplished using UAS and the orbit requirements for each particular intelligence type.

Synthetic Aperture Radar. Synthetic aperture radar (SAR) was developed in the 1950s. It is used to image large areas at very high spatial resolution. In radar, an antenna transmits and receives radio waves to illuminate a scene. The range resolution is determined by the bandwidth of the signal transmitted, and the cross-range resolution is determined by the length of the antenna. An airborne antenna provides a good vantage point but physically limits the length of the antenna. For SAR, a small antenna is put in motion, transmitting and receiving signals to synthesize a much larger antenna, for example, an antenna several kilometers long, to achieve good cross-range resolution. SAR

3107 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

depends on specific algorithms to reconstruct the scenes into images. Most of these algorithms assume a straight flight path; any deviations are treated as motion error (Berens 2006).[13] A platform using SAR would fly in straight paths at a constant altitude with the swath width of the sensor as the width between passes.

Figure 3.4
SAR Requires a Straight Flight Path



SOURCE: Image from FAO Fisheries and Aquaculture Department (1988).

Ground Moving Target Indicator. Ground moving target indicator (GMTI) is another intelligence collection technique that leverages radar. GMTI detects, locates, and tracks targets that are moving on the surface. For GMTI, the Doppler shift in the frequency of radar returns from a moving target is used to discriminate it from the static surface background (Dunn, Bingham, et al. 2004). GMTI was originally designed to distinguish movements of large objects, such as tanks and trucks, for battle space awareness. When employing GMTI, the platform is typically flown parallel to the area of interest in order to have the most coverage of the area. This results in an elliptical orbit with a small minor axis. A GMTI orbit derived from examples during Desert Storm is shown in Figure 3.5.

[13] Algorithms for SAR image formation using alternative flight paths have been developed, but are not commonly used (see Soumekh, 1999).

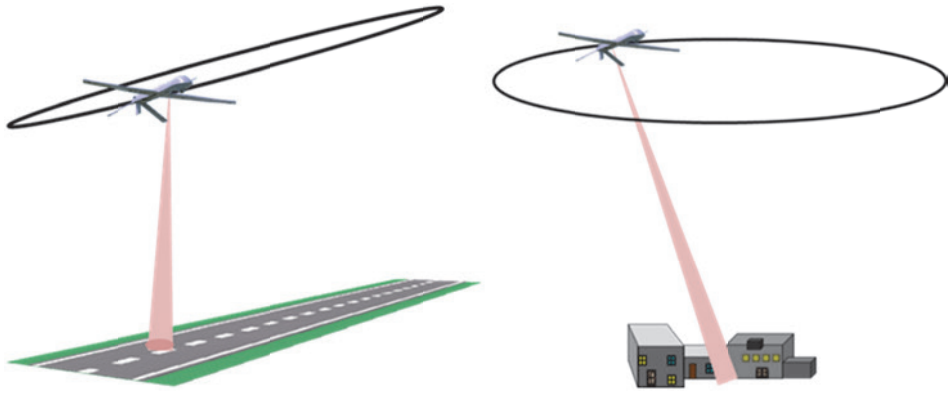
Figure 3.5
GMTI Is Often an Elliptical Orbit

SOURCE: Dunn, Bingham, et al. (2004).

Imagery. By *imagery*, I mean still images generated from an optical sensor. Among other things, imagery is useful in identifying and providing visual information on targets of interest. In airborne applications, aircraft altitude and slant range affect the resolution and image quality. The path or orbit is not prescribed by the intelligence type, but is more dependent on the target deck[14] and efficiently prosecuting all targets. The target deck is likely different each day. A unique scheme of maneuver is developed for each mission; it outlines a track to capture all the requested imagery at the necessary resolution, in the most efficient manner possible. Figure 3.6 shows an example of a scheme of maneuver for imagery.

[14] The target deck or collection deck is a list of all the targets that need to be collected against.



3109 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 3.6
IMINT Does Not Dictate an Orbit

Full-Motion Video. The demand for full-motion video (FMV) grew immensely during operations in Iraq and Afghanistan. FMV sensors are typically a turreted pod with dual electro-optical (EO) and infrared (IR) camera systems that permit operation across day and night. FMV is used in many tasks, with the task often determining the orbit flown. This analysis focuses on two common FMV orbits, a racetrack orbit and a circular orbit. A racetrack orbit would be used for a task such as monitoring a road for IED activity. A circular orbit would be used for a task such as providing 360-degree coverage of a compound prior to or during a raid. Figure 3.7 illustrates both of these orbits.

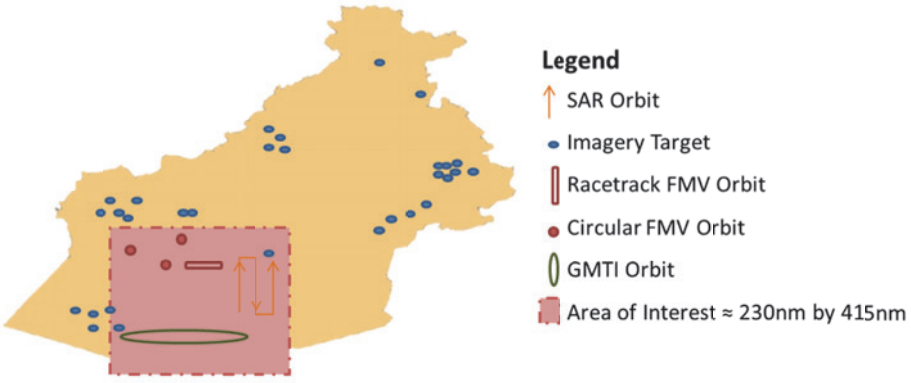
Figure 3.7
Racetrack Orbit for Road Surveillance and Circular Orbit for 360-degree Coverage of Compound

3110 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MISSIONS HAVE A PRIMARY INTELLIGENCE FOCUS

Today, most UAS are tasked as ISR assets through the Combined Air Operations Center (CAOC). The CAOC takes in all the requests for ISR support, prioritizes the requests, and assigns the available air assets to fulfill the requests (U.S. Air Force 2011). Although many UAS are equipped with multiple sensors, when they are tasked by the CAOC, they are usually tasked with one intelligence type as their primary mission, for example, IMINT-prime or SIGINT-prime (AFISRAI-14-153 2009). The mission is planned to maximize the quality of the intelligence gathered. This results in a plan to collect the intelligence targets from an optimum altitude, velocity, distance, or angle to the target. In this way, the intelligence needed drives the orbit the platform will fly when collecting the intelligence.

SIGINT is typically provided by manned assets (Thompson 2004). UAS are predominately tasked for their imagery sensors, such as FMV. If a T/FDOA capability was added to UAS, multiple platforms would need to receive the signal in order to determine the probable location using T/FDOA geolocation. Given the high demand for FMV collection and the requirement for multiple platforms, T/FDOA geolocation would likely be accomplished as a secondary mission. The accuracy of T/FDOA geolocation is sensitive to the geometry between the collectors and the target. As discussed above, the different intelligence types dictate specific tracks or orbits that must be followed with different levels of rigorousness. The goal of this section is to show what level of accuracy might be expected if T/FDOA geolocation was included as a secondary mission.



Scenario for Modeling Accuracies

During a day of operations, there will likely be several different intelligence collection missions operating within the same geographic area. Figure 3.8 shows an example of all the different intelligence missions that might be within line of sight of the same targets. There might be a standing target deck for IMINT collections, represented by the blue dots, from a manned or unmanned platform. JSTARS (the joint surveillance and target attack radar system) might be tasked to use its

3111 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

GMTI radar for border surveillance, shown as the green ellipse. Several MQ-1/MQ-9s might be using FMV to provide over-watch of a house raid, follow a high-value target, or cover a stretch of road to monitor for IED activity, as represented by the red circles and red ellipse. An MQ-9 equipped with SAR might be collecting high-quality terrain data or doing coherent change detection, shown by the orange track. All of these platforms might be operating within line of sight of a target emitter and capable of opportunistic collection on this target emitter, represented by the red box.

Figure 3.8
Operations Might Be in the same Area

For this analysis, I assumed that the T/FDOA system is capable of operating out to the radar horizon.[15] The radar horizon is dependent on the altitude of the platform. The altitudes that were used in these scenarios and the resulting geometric and radar horizon are listed in Table 3.1.

[15] If externals are collected, a system is theoretically capable of detecting signals out to the radar horizon.

3112 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 3.1
Line of Sight Limitations

Altitude16 (kft/km)	Geometric Horizon (nm/km)	Radar Horizon (nm/km)
15 (4.572)	130 (241)	151 (280)
20 (6.096)	151 (280)	174 (322)
25 (7.620)	168 (311)	194 (359)
30 (9.144)	184 (341)	213 (394)

This analysis used five scenarios, with four different orbit geometries modeled: Circular FMV, Racetrack FMV, SAR, and GMTI. The focus was on intelligence types where the orbit is repetitive and must be followed with some level of rigorousness. For this reason, still imagery was not included in this analysis. As discussed above, the track an imagery mission uses is dependent on the collection target deck for that specific mission. It therefore does not require a repetitive orbit, and could be altered to participate in a T/FDOA collection. The scenarios featured two platforms flying to conduct their primary mission. The five scenarios that were modeled are summarized in Table 3.2.

Table 3.2
Scenarios for Orbit Geometries

Scenario	Orbit of #1	Orbit of #2
1	Circular FMV	Circular FMV
2	SAR	Circular FMV
3	SAR	Racetrack FMV
4	GMTI	Circular FMV
5	GMTI	Racetrack FMV

I varied the type of orbit flown, according to the above scenarios, and the parameters of the orbit. These parameters were meant to exemplify a few typical orbits.[17] The inputs for the orbits are summarized in Table 3.3.

[16] Calculated as slant range based on spherical earth, with 0 deg elevation angle.

[17] These parameters were developed in conjunction with members of the dissertation committee. The purpose was not to outline specific tasks and targets for each orbit, but to provide a few notional but practical examples of orbit geometries.

3113 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 3.3
Orbit Inputs

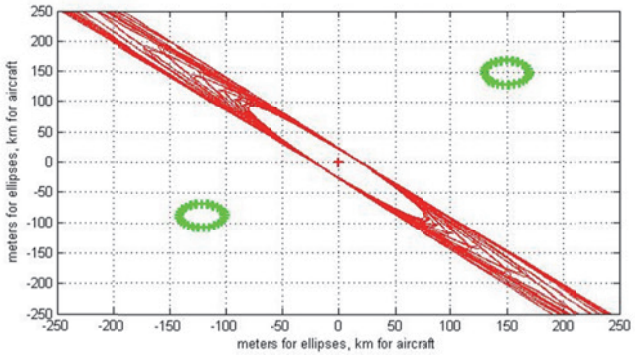
Parameters	100-150km, 20-50km	150km path, 2km turn	40-50km, 5-10km	20km or 10km radius

*Speed is constant; however, velocity is calculated based up the orbit.

The other parameters for the T/FDOA Accuracy Estimation Model were held constant throughout this analysis. In preliminary analysis, these parameter values were chosen as a representative case.[18] These parameters, values, and an explanation are listed in Table 3.4.

Table 3.4
Other Model Parameters held Constant

Parameter	Value	Explanation
Target Location	[0,0,0]	Orbits were rotated around target to account for geometric differences in target location
Number of T/FDOAs	1 TDOA, 1 FDOA	This represents a lower bound on the expected accuracy. At least 1 TDOA and 1 FDOA is required for T/FDOA geolocation.
Frequency of Signal	164 MHz	A representative VHF signal
Bandwidth of signal	25 kHz	A representative noise bandwidth
Integration Time	30 sec	Time for integration of signals
Power	7 dBW	5W EIRP, a typical power for a VHF push-to-talk radio
Sigma P	10.2m	Based on GPS P(Y) code error
Sigma V	5cm/sec	Based on typical error for GPS or low grade IMU
Sigma T	100×10^{-9} sec	10 times the worst case GPS clock synchronization error
Two D	1	Indicator for if third dimension (altitude) is known



For each scenario, I modeled 10 cases in which the orbit parameters and orbit distances to the target were varied. Each case was run 50 times with a randomized starting point on the orbit for both

[18] There is a discussion of the impacts of parameters/errors in Chapter Two.

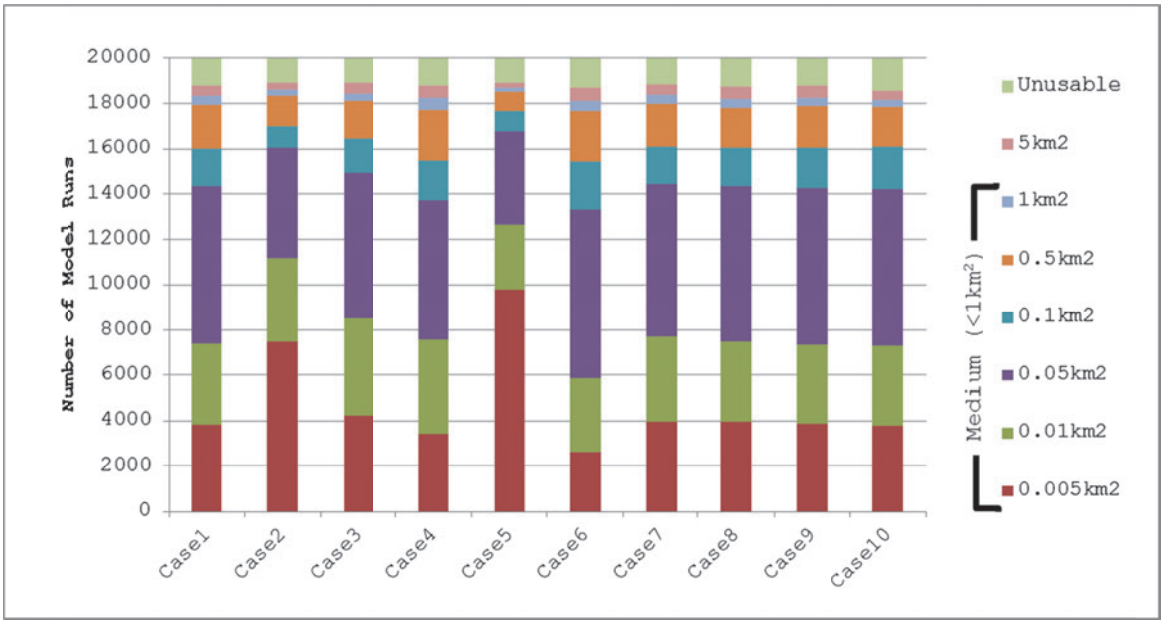
3114 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

platforms. Within each run, one orbit was rotated around the target to account for differences in geometric orientation and velocity relative to the target. At each rotation point, the orbits were run for 25 position steps, resulting in 200,000 model runs for each scenario. The full results for each scenario are included in Appendix B. An example from Scenario 1: Two Circular FMV Orbits is shown in Figure 3.9.

Figure 3.9
Example of Geolocation Accuracies from Scenario 1

In this example, the target is represented by the red cross. The two UAS orbits, represented in green, are circular orbits centered at (150km, 150km) and (-75km, -125km), respectively. Each red ellipse represents a T/FDOA geolocation in square meters resulting from those orbits. The geolocation is very sensitive to geometry.

Results from Orbit Geometries



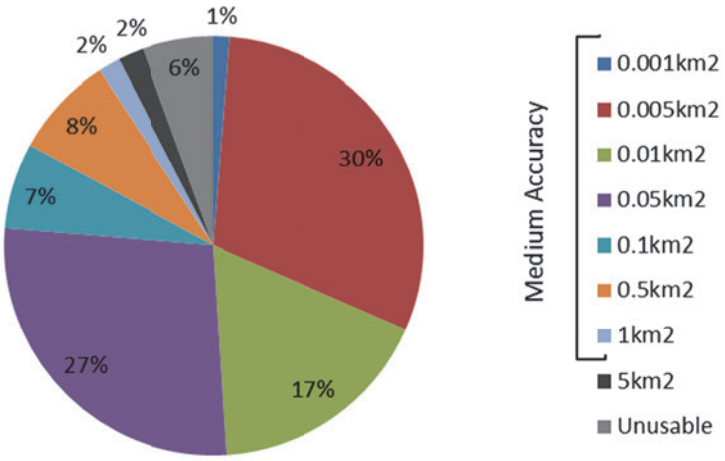
The results from Scenario 1: 2 Circular FMV Orbits indicate that, in most instances, very good accuracies can be achieved with this orbit configuration. A histogram of the area of the ellipses for each case is shown below in Figure 3.10. However, even when the primary mission orbits are placed closely together, there is still enough diversity in the geometry to result in a majority of medium accuracy geolocations.

Some configurations achieved overall better accuracies than others, for example, Case 5. The number of low and extremely low accuracies, those with an area greater than 1km^2, was fairly consistent and low across all the cases. However, examining only those

3115 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

geolocations within at least medium accuracy (<1km^2), there is not much stability between the cases. The placement of the orbits in relation to each other drives some areas to be significantly better than others. However, even when the primary mission orbits are placed closely together, there is still enough diversity in the geometry to result in a majority of medium accuracy geolocations.

Figure 3.10
Histogram of Areas from Scenario 1



Examining these results categorized only by the area of the ellipse shows that over 90 percent of the geolocations resulted in medium (<1km^2) accuracy. Almost 75 percent of the geolocations had an area less than 0.05km^2, and a little under a quarter were actually within 0.005km^2. Of the approximately 8 percent of geolocations greater than medium accuracy, about 2 percent were of low accuracy (<5km^2), and 6 percent were unusable, resulting in no solution. The situations that did not result in a geolocation were the result of poor geometry.

The results from Scenario 1 indicate that, in most cases, the geometry created by the orbits optimized for FMV intelligence collection will still yield acceptable accuracies. Individually, the other scenarios had similar results. Results for all the scenarios are

3116 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

included in Appendix B. Tabulating the data across all the scenarios, the outcomes remain consistent.

Figure 3.11
Results for 5 Scenarios: Percent Distribution of Error Ellipse Areas

The analysis shows that T/FDOA geolocation is robust to the various orbit combinations. In these partly random, non-optimized scenarios, medium-level accuracy geolocations were achieved consistently. Approximately 90 percent of the geolocations were medium accuracy. Occasionally, the geometry will be poor enough to cause geolocation to fail. The geolocation failures were spread fairly evenly across each scenario, and amounted to approximately 6 percent of the total geolocations. In the instances of poor geometry, the two orbits were usually very close to each other, causing small differences in both the timing and the frequency. Infrequently, the geolocation resulted in high accuracy ellipses of less than $100m^2$. Ideally, high-accuracy geolocation would be preferred each time; however, these results can be thought of as an upper bound. For this analysis, I used only two aircraft, the minimum required for T/FDOA geolocation. More sensors would, in general, improve the accuracies. This analysis shows that as a secondary mission, on a completely non-interference basis, T/FDOA geolocation could be expected to provide at least medium-level accuracy in most instances. This level of accuracy could likely be

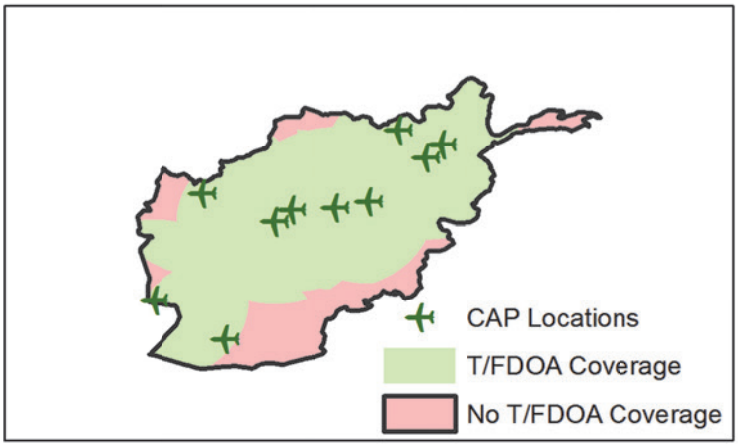
3117 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

improved with the addition of more sensors or including minimal planning for T/FDOA geolocation to coordinate orbit start times, orbit locations, etc.

WOULD UAS OPERATE CLOSE ENOUGH TO LEVERAGE T/FDOA?

To use T/FDOA geolocation, we need at least two platforms with line of sight to the target emitter. I used a model to characterize whether UAS fly close enough to use T/FDOA geolocation in Afghanistan. By FY13, the Air Force plans to have 65 available combat air patrols (CAPs) of MQ-1/9s (Schanz 2011). I used the ArcGIS software to model the CAPs and their line of sight ranges. The model randomly distributes the CAPs throughout the area of interest. It first determines the areas that are within line of sight of each CAP. These areas represent the potential coverage area for SIGINT. Then, it finds the areas that can be seen by multiple CAPs. These areas represent the potential regions for T/FDOA geolocation. The model does not taken into consideration limitations on line of sight caused by terrain. The model is explained in Appendix C. Air assets are typically apportioned according to a weight of effort (Joint Chiefs of Staff 1994). A weight of effort during the height of Operation Enduring Freedom and Operation New Dawn might have been 60 percent Afghanistan, 30 percent Iraq, and 10 percent for the rest of the world. I focused on Afghanistan as the bounding geometry.[19] I modeled the presence of 5, 10, 15, and 20 CAPs in the air simultaneously at four different altitude levels.[20]

As mentioned above, T/FDOA geolocation requires at least two aircraft. I first examined the potential T/FDOA geolocation areas or those areas covered by at least two CAPs. An example of the coverage available with 10 CAPs is shown in Figure 3.12, with green representing areas that are covered by at least two CAPs, red representing areas



[19] I use Afghanistan for the bounding geometry, however I ignore the line of sight limitation of terrain. The results would be similar for any country or area of interest of similar size to Afghanistan.

[20] By FY13, the Air Force plans to have 65 available combat air patrols (CAPs) of MQ-1/9s (Schanz, 2011). These would be simultaneously available.

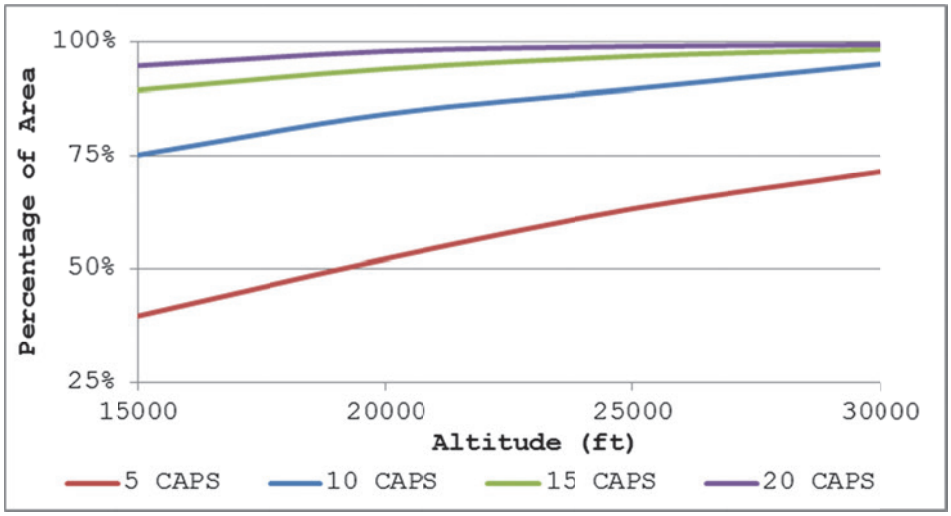
3118 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

that are covered by only one CAP, and white representing areas with no coverage.

Figure 3.12
Example Coverage with 10 CAPS

Coverage improves as either altitude or the number of CAPs is increased. For example, the line of sight from five CAPs at 30,000ft would be able to cover almost the same area of Afghanistan as 10 CAPs at 15,000ft. These relationships are shown in Figure 3.13 and Figure 3.14.

Figure 3.13
Area Covered by Line of Sight as Altitude Increases



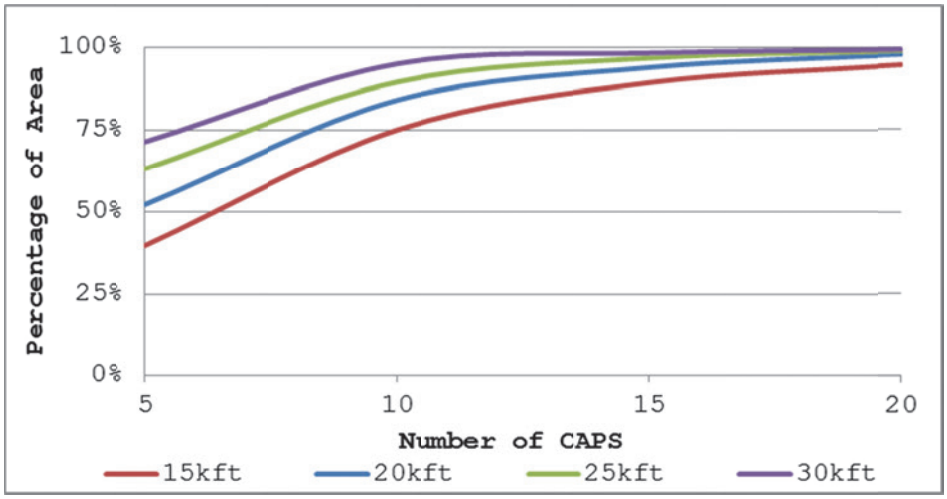


Figure 3.14
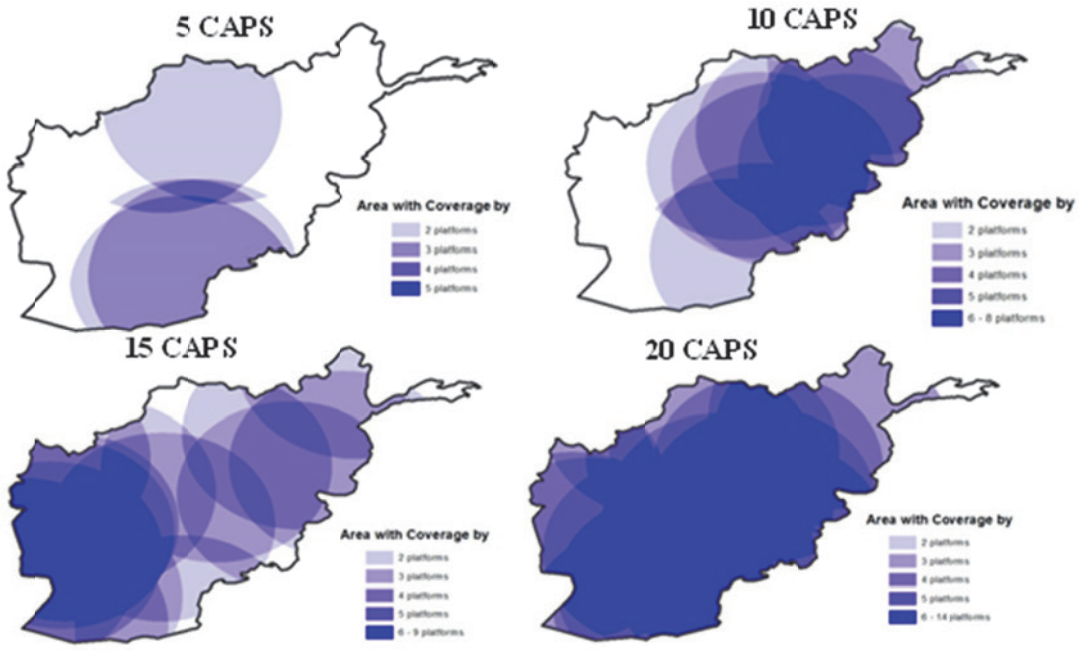
Area Covered as CAPs Increase



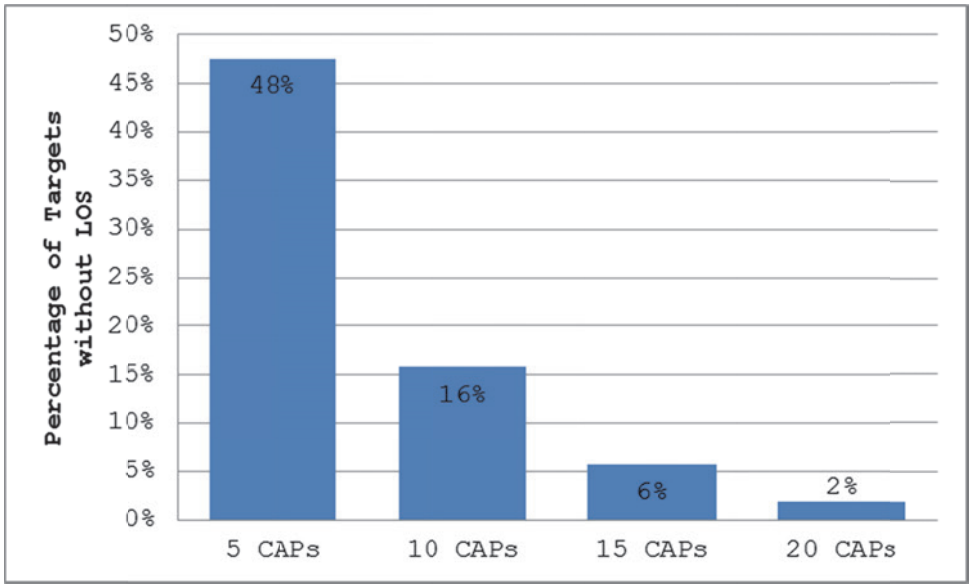
This analysis shows that a small number of UAS CAPs can provide T/FDOA coverage throughout most of an area the size of Afghanistan. Small increases in the number of CAPs and increasing the altitude significantly improves the amount of area covered.

In general, the accuracy of T/FDOA increases as the number of platforms participating in the geolocation increases. Though the accuracy is good when there are collections from two to three platforms, it can be remarkably better if more platforms are involved.[21] We can use the ArcGIS model to further determine exactly how many CAPs cover the area. Figure 3.15 below shows an example of the overlapping areas geographically for one example of 5, 10, 15, and 20 CAPs at an altitude of 20,000ft.

[21] Each new platform increases the number of TDOAs and FDOAs that are available for geolocation.

3120 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 3.15
Coverage for 5, 10, 15, and 20 CAPs at 20,000ft



Increasing the number of CAPs available greatly increases the amount of area seen by more than two aircraft. As the area seen by four and five or more aircraft increases, the geolocation accuracy will also significantly increase. T/FDOA geolocation could be performed throughout most of an area the size of Afghanistan using only 20 CAPs; however would the accuracy of geolocations from these small numbers of CAPs be useable?

To test this, I used a combination of geospatial analysis with the T/FDOA Accuracy Estimation Model. I randomly distributed 20 targets throughout Afghanistan. The random location of CAPs from the previous analysis and the layer of random targets were used as inputs in the T/FDOA Accuracy Estimation Model. First, I examined the number of targets that were not within line of sight of at least two CAPs. These targets could not be found using T/FDOA geolocation. The number of targets without line of sight decreases as the number of CAPs increases, as shown in Figure 3.16. At 20 CAPs, the average number of targets that were unavailable was less than one.

3121 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

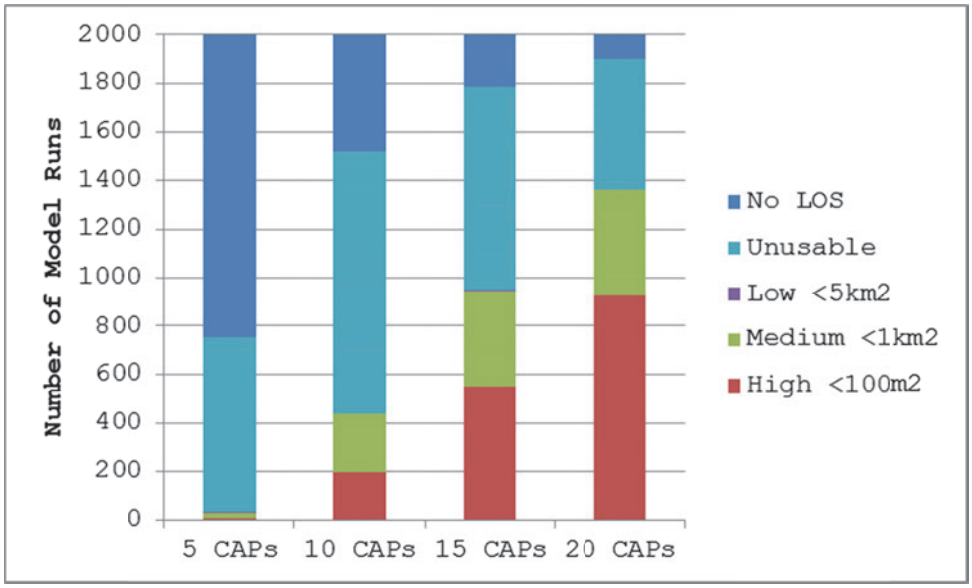
Figure 3.16
Average Percentage of Targets Without Line of Sight at 20,000ft

Next, I examined the accuracies for the targets that were within line of sight using the T/FDOA Accuracy estimation tool.[22] With only five CAPs, only a handful of targets are found with medium or high accuracy. With 10 CAPs at 15,000ft, approximately 25 percent of the targets were located with medium or high accuracy. As the number of CAPs increases or as the altitude increases the number of targets found with medium or high accuracy also increases. With 20 CAPs at 30,000ft, just under 95 percent of the targets can be found with medium or high accuracy. The number of targets found with high accuracies increases more than the number found with medium accuracy. Figure 3.17 and Figure 3.18 below show these relationships for geolocations at both 15,000ft and 30,000ft.

[22] I used the same parameters for the other model inputs as listed in Table 3.4.

3122 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 3.17
Results of Geolocations from 15kft



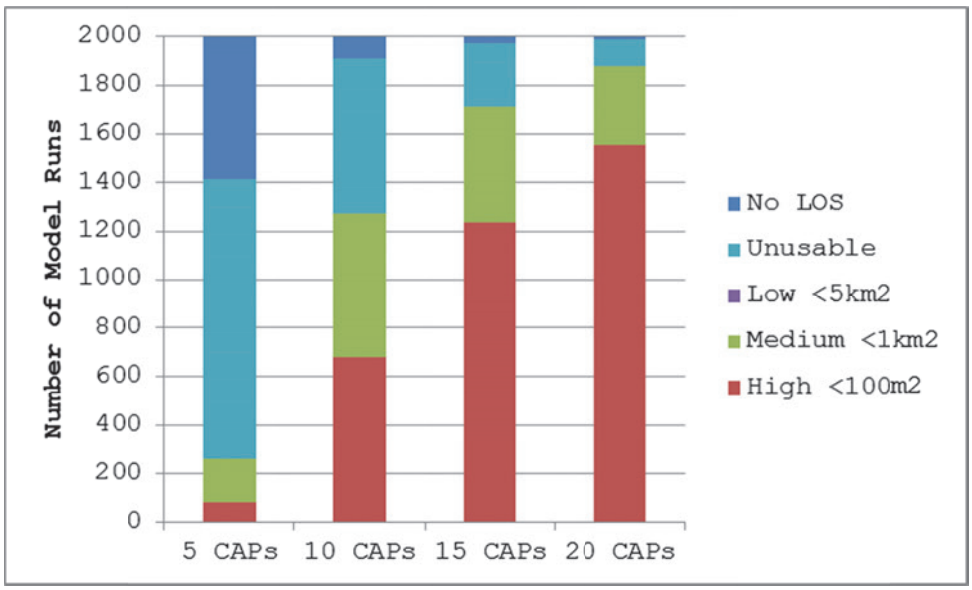


Figure 3.18
Results of Geolocations from 30kft

The results from the analysis indicate that UAS operating in Afghanistan or another similar sized area would be close enough to use T/FDOA throughout most of the area. The geolocations from these UAS have the potential to be very accurate. A few additional UAS CAPs

3123 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

greatly increases the likelihood of successful, accurate geolocation. Increasing the altitude at which the UAS are flown also has a significant impact on the amount of medium and high accuracy geolocations. In practice, there would be a trade-off between increasing the altitude for geolocation and impacting the spatial resolution of the primary intelligence.

CONCLUSION

The analysis shows that T/FDOA geolocation would be a very useful capability on UAS. When contrasted with direction finding, T/FDOA is more robust in several key ways that make geolocation of signals like push-to-talk radios less challenging. T/FDOA needs only a non-directional antenna, which is less SWAP restricting. T/FDOA is nearly instantaneous, and the accuracy degrades less with range. I explored the two major limitations of T/FDOA geolocation, sensitivity to the geometry of the receivers and the requirement for multiple equipped platforms, using geospatial analysis and the T/FDOA Accuracy Estimation Tool. The results indicate that T/FDOA would provide high-quality geolocation accuracy even as a secondary mission. The different orbit geometries have only minor impacts on the geolocation accuracy. In all of the orbit combinations, medium-accuracy geolocations accounted for nearly 90 percent of all the geolocations. Many of these medium-accuracy geolocations were closer to the high accuracy threshold.

I can conclude that the geometries created by the different orbit combinations are sufficient for quality T/FDOA geolocations. For T/FDOA geolocation to be possible, the participating platforms must be within line of sight of the same target. I explored this question and determined that with a fraction of today's available UAS CAPs, there would be enough T/FDOA coverage to cover most of an area the size of Afghanistan. The accuracies available from these UAS CAPs were of extremely high quality. With only 20 UAS CAPs at 30,000ft, almost 95 percent of the targets were found with high or medium accuracy.

This research used Afghanistan as the bounding geometry. The results would hold for countries of similar size. Modeling the impact of line of sight limitations caused by terrain features was not the

3124 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

point of this research. In general, terrain can impact the line of sight for emissions. Some areas that would be seen with a flat earth would be blocked from view. These blockages would reduce the area for T/FDOA coverage and could impact the number of targets found.

T/FDOA geolocation would be useful addition that would provide supplementary geolocation capability and capacity, while still enabling the UAS assets to continue to conduct their current missions.

3125 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

4. What Is Needed to Use T/FDOA Geolocation?

This chapter focuses on what would be needed for T/FDOA geolocation to be implemented on UAS. To be T/FDOA-geolocation-capable, the UAS will need to be equipped with a SIGINT system. I first outline specific requirements for a SIGINT system capable of T/FDOA. Then, I investigate the first T/FDOA capable system, AT3, to uncover technological and design challenges. Using AT3 as a guide, I detail integration on UAS and explain some challenges. An analysis of the costs of the SIGINT system is outside the scope of this work. A SIGINT sensor system on UAS will bring additional data that needs to be processed, exploited, and disseminated (PED) as intelligence. PED is often very manpower-intensive. I estimate the manpower needed for T/FDOA PED and the cost implications of the new manpower.

Equipment for Platforms to Be Capable of T/FDOA Geolocation

Two key choices to be made in designing a SIGINT system are the antenna and the receiver(s) to be used. These two choices drive the capabilities of the system. The system is usually described by several parameters, which are listed in the Table 4.1.

Table 4.1
System Parameters

Term	Definition
Gain	The increase in signal strength (dB) as the signal is processed.
Frequency coverage	The frequency range over which the system can transmit or receive signals.
Polarization	The orientation of the electric field of the radio wave.
Beamwidth	The angular coverage of the antenna (degrees).
Efficiency	Ratio of power radiated by the signal to power absorbed by the system.
Bandwidth	The instantaneous bandwidth of a signal that can be collected.

SOURCE: Adapted from Adamy (2001), p. 32.

For SIGINT tasks, the antenna choices are dominated by the ability to provide the required angular coverage (directional vs. non-

3126 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

directional), polarization, and frequency coverage. The receiver choice can be influenced by the information required for the task.

Channelized and digital receivers are the state of the art and the most capable. In previous years, they were considered too expensive and too SWAP-restrictive (Adamy 2001). Digital receivers offer several benefits over analog receivers that are important for a T/FDOA system. Additional channels are low-cost due to economies of scale (Hosking 2006). Digital receivers are low-powered with improved stability and accuracy and high reliability compared with analog receivers. In addition, the programmable nature of digital receivers means that often a software update is all that is needed to upgrade the receiver.

Requirements for T/FDOA

For a system to be capable of T/FDOA, it must first receive the signals. The antenna choice will be primarily driven by the signals of interest. For example, if the targets of interest are push-to-talk radios, then the antenna should provide the requisite frequency coverage of the UHF/VHF bands. A T/FDOA system must also be able to measure both the time of arrival and the RF frequency, so a simple receiver is not enough. Besides geometry, the largest drivers of T/FDOA accuracy are usually the timing synchronization error and the position errors. A T/FDOA system therefore needs the highest-quality timing and position inputs. T/FDOA requires coherent sensors. In this context, *coherent* has a broader definition than the traditional use of the term. A coherent sensor must "provide precise control of amplitude, frequency, and carrier-phase offsets, and must also take into account propagation delays" (Kosinski 2003). It must also provide precise location, timing, and axial orientation to every other sensor that will participate in the T/FDOA calculation. Since T/FDOA is a cooperative technique with geographically separated receivers, a data link is required to pass the data needed to calculate each T/FDOA.

AT3 System

The AT3 system is the first T/FDOA capable system designed from scratch. It was designed to be functional on any tactical platform. It

3127 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

leveraged and created new technology to create an affordable package with minimal SWAP burden. The goal for AT3 was an accuracy of at least 50m circular error probable (CEP) at distances greater than 50nm in less than 10secs (Highnam 2001). The T/FDOA techniques require precise measurement of time and frequency as well as transferring that information between participating collectors and conductors of the requisite PED. The precision requirements drive the system components used in AT3. Table 4.2 shows the key components of AT3 needed to accomplish T/FDOA and their functions within the system.

Table 4.2
AT3 Sensor System

Component	Function	Key Features
Radome	Protect antennas from weather, reduce drag on aircraft	Broad band
Antennas	Transduce RF energy into system	Broad band, wide field of view
RF Down Converter	Translate RF signals to an intermediate frequency	Broad band, low noise, wide IF bandwidth
Digital Receiver	Extract signal information from IF	Wide band, high-speed ADC, high sensitivity
Local Oscillator	Provide reference signals for system and RF down-conversion	Low phase noise, narrow phase lock bandwidth
GPS	Provide time, frequency and position information	All-in-view receiver
Frequency and Time Board	Synchronize AT3 with GPS	System clock, GPS time and frequency transfer
Signal Processing	High sensitivity	High-resolution channelizer, many narrow band detectors
	Precision Time	Leading edge measurement

3128 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

	Measurement Precision Frequency Measurement Geolocation	Phase measurement TDOA, FDOA, hybrid, derivative of GPS equation, erroneous measurement filtering
Data Link	Exchange data between aircraft	JTIDS, efficient slot utilization
AT3 INSTRUMENTATION SYSTEM		
Cesium Clock	Time and frequency reference	Primary standard
Time Interval Analyzer	Time benchmark between system clock and Cs Clock	
Frequency Measurement System	Short time frequency measurement	Hybrid phase noise/TIA, short time frequency benchmark between reference LO and Cs
Secondary GPS	Time Space Position Information (TSPI)	Commercial survey quality, support kinematic survey of aircraft

SOURCE: adapted from Raytheon (2004), p. 18.

In designing the AT3 system, DARPA encountered several technical challenges that needed to be overcome. The long-range goal of at least 50nm meant that an extremely sensitive receiver was needed. To provide this sensitivity, a digital receiver with a low noise multi-octave RF down converter was used (Raytheon 2004). As mentioned above, T/FDOA requires extremely precise knowledge of position and velocity. DARPA integrated an inertial navigation system (INS) with GPS to determine the precise aircraft state vector (Highnam 2001).

There were also issues with meeting the time and frequency transfer requirements. A Kalman filter was used to help align the data from the analog-to-digital converter into GPS time reference (Raytheon 2004). To verify the accuracy of time and frequency transfer, AT3 employed cesium clocks on each platform that were calibrated before and after each flight (Raytheon 2004). There were no algorithms for tagging

3129 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

time of arrival and frequency of arrival at the low SNR levels that would be encountered. The engineers designed a hybrid algorithm that accurately tagged the leading edge as well as identified potential issues within the pulse (Raytheon 2004). Finally, AT3 was required to use the existing Joint Tactical Information Distribution System (JTIDS) as the data link to pass information. JTIDS is a widely used system with limited available bandwidth. The solution was to reduce the data transferred by limiting the number of platforms involved (Raytheon 2004). Only two collectors passed data to a third master platform for each geolocation, reducing the bandwidth needed for T/FDOA. The AT3 system resolved many key challenges for a T/FDOA system.

UAS Integration

T/FDOA can be accomplished with a non-directional antenna. UAS are already equipped with several non-directional antennas for communications purposes that could be leverage by a T/FDOA system. For example, the MQ-1B Predator is equipped with an AN/ARC-210 digital communication system that has a frequency range of 30-941MHz, which includes a UHF/VHF antenna on the top side and under side of the platform (ACC Public Affairs 2012; Rockwell Collins 2012). The presence of a UHF/VHF antenna would allow the UAS to host a T/FDOA system without any external modification to the platform. Following the path set by AT3, a digital receiver would be the best choice because of its performance capabilities. The system would need to be integrated with GPS/INS to provide the needed precision for the aircraft state vector.

The reliance of T/FDOA on precise measurements means the design of the system can have significant influence on the accuracy of geolocation. The location of the system in relation to the GPS receiver can potentially impact the accuracy, especially if the platform will be turning or banking frequently. For example, if a system was located on the wing of the aircraft while the GPS receiver was located centrally on the body of the aircraft, the input of the receiver positions will be inaccurate. If the aircraft flew straight, this difference could be easily factored into the T/FDOA calculation. However, if the aircraft is turning or banking, there could be a difference in all three

3130 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

coordinates (x,y,z) that could not be easily corrected. The inaccuracy with which the receiver position is known can create geolocation ellipses that misstate the accuracy. The severity of these misstatements increases as the geometry degrades.

Figure 4.1
Geolocation Error Ellipse Can Be Influenced by Location of GPS in Relation to Receiver

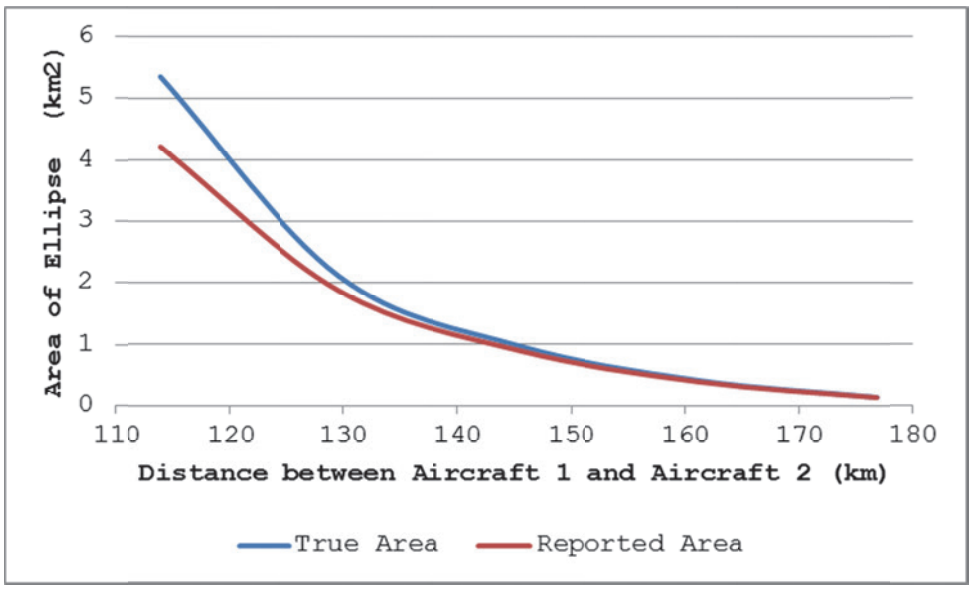

Figure 4.1 shows an example how the area of the ellipse can be misstated due to the position of the receiver in relation to the GPS receiver. In this example, two aircraft are used for the geolocation. One aircraft is in a simulated 30 deg bank. The banking aircraft is moved closer to the second receiver along a diagonal from the target location. Initially, the reported area overstates the true accuracy. However, as the geometry degrades, the reported area begins to understate the true accuracy.

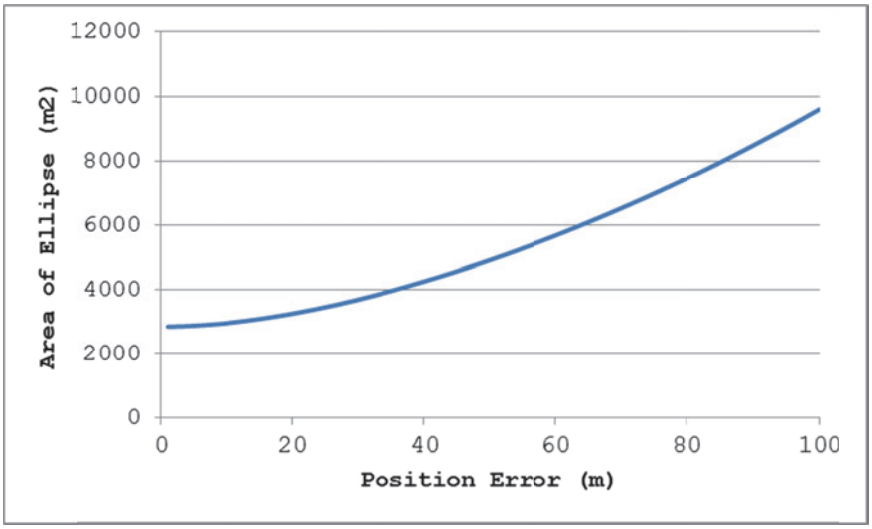
The time interval for the reporting of the aircraft state vector can also influence the geolocation accuracy. These aircraft are moving at a typical speed of 200 knots, or about 100m/s in any given direction. The reporting frequency of the aircraft state vector can influence the accuracy of the state vector data, which in turn impacts the accuracy of geolocation. We can represent the impact of the

3131 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

reporting frequency as a change in the error terms for position and velocity. Figure 4.2 and Figure 4.3 show the impact of each error as it is increased and all other inputs are held constant.

Figure 4.2
Size of Error Ellipse Increases as Position Error Increases



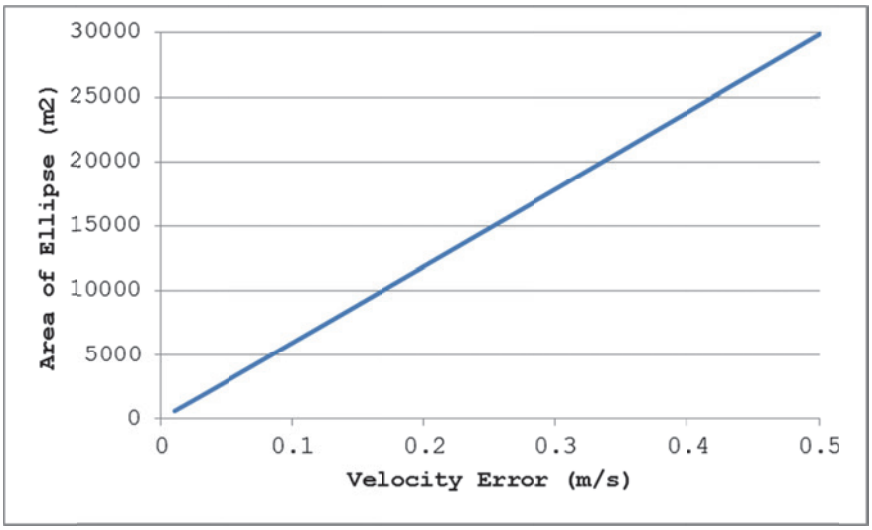


Figure 4.3
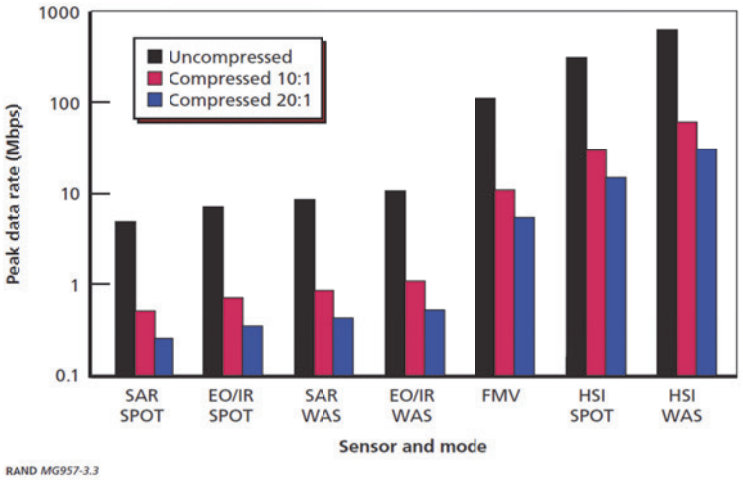
Size of Error Ellipse Increases as Velocity Error Increases



Small inaccuracies in the velocity and position measurement can lead to significant increases in the ellipse size. It is important to minimize the error contribution with quality system design.

3132 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The constraint for using JTIDS data link forced AT3 to severely limit the number of collectors involved in the geolocation to reduce the bandwidth needed. A T/FDOA system on UAS would not be restricted to a similar solution because off-board geolocation calculation could take place at a PED center. For data dissemination and C2, UAS are currently operated with a constant data link. Two types of links are primarily used, a line-of-sight link or a beyond-line-of-sight link using satellite communication (SATCOM). The Army uses a line of sight data link with its RQ-7 Shadow that uses a C-band link to send data to the ground control station and then forward to users. A line of sight data link is a tether, restricting operations to within line of sight of the ground control station. The Air Force uses satellite communication (SATCOM) to send data back from its MQ-1s and MQ-9s (FY09-40 UAS Roadmap Undersecretary of Defense for AT&L 2009). The Reaper and Predator transfer data back to the PED centers using Ku-band SATCOM. The data from T/FDOA would piggyback on the intelligence data collected from the primary mission. Typical data rates for IMINT sensors are shown in Figure 4.4.

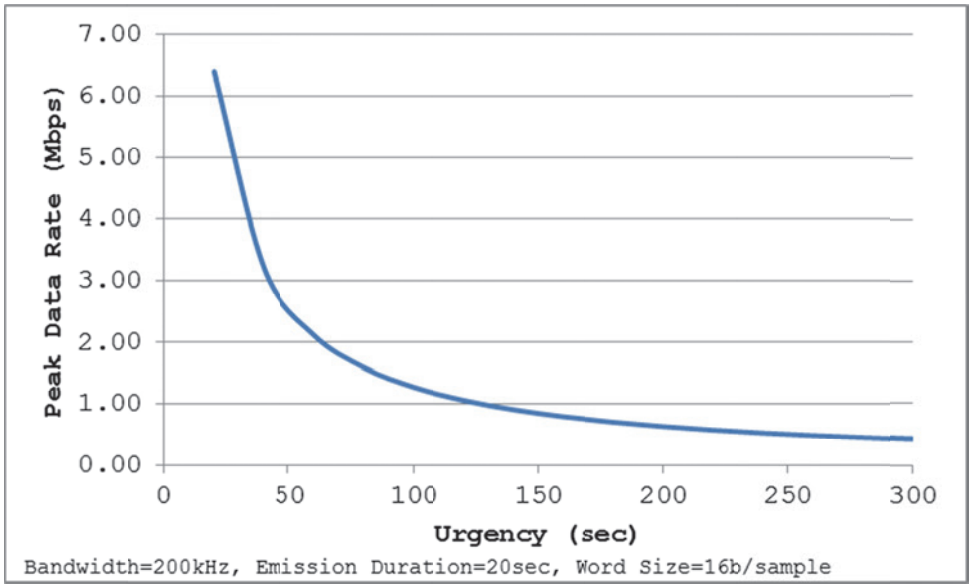
Figure 4.4
Typical Peak Data Rates for IMINT Sensors

SOURCE: Alkire, Kallimani, et al. (2010).

I evaluated the data rate that might be created from a T/FDOA system on UAS. A number of factors influence the data rate, including

3133 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the bandwidth monitored, the duration of the emissions, and the periodicity of emissions on each channel. For this analysis, I assumed an emission lasts for 20 seconds, with one emission every ten minutes.[23] A typical VHF push-to-talk radio would have a 25kHz bandwidth per channel.[24] A storage buffer would be required to record the signals until an analyst determined that a geolocation was needed. I assume that the buffer would need to be at least large enough to hold one period's worth of emissions and that thresholding is used.[25] For each 25kHz increase in the bandwidth monitored, the buffer size increases 16Mb. The peak data rate is influenced by the speed with which the data is needed; I call this the urgency. Examining the peak data rate as the urgency changes shows that a quick time requirement can drive the date rate. Figure 4.5 shows the relationship between urgency and the peak data rate. I use an urgency of 90 seconds for the remainder of the analysis.



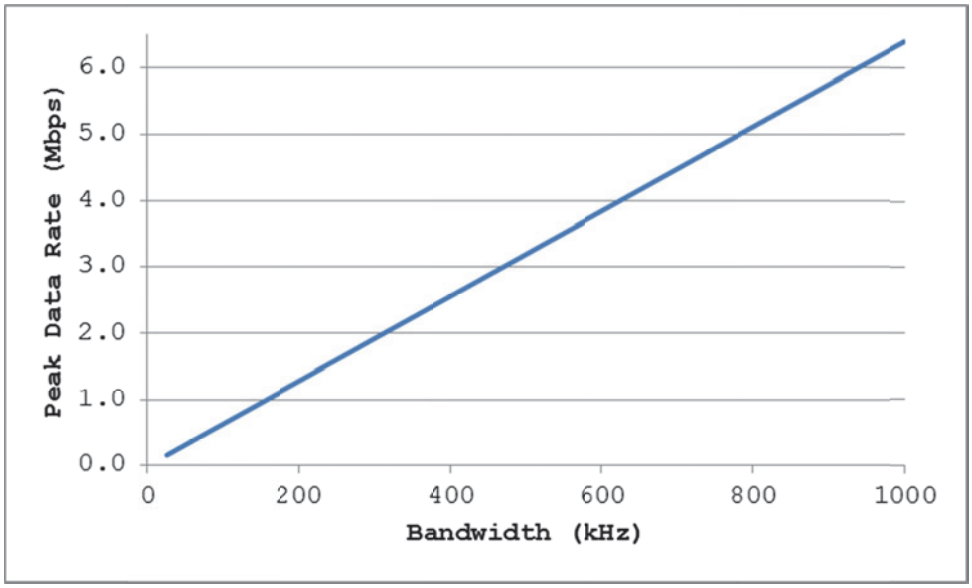
[23] The emission may last longer than 20 seconds. The entire emission is not needed to calculate a T/FDOA. Twenty seconds is more than adequate for the calculation in typical applications.

[24] VHF/UHF radios can be narrowband-capable with 12.5kHz channels. Narrower channels decreases the sampling rate, which in turn decreases the storage needed for one period of emissions and the peak data rate.

[25] Recording only occurs when a signal has been detected. Therefore, silence is not recorded.

3134 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 4.5
Peak Data Rate as Urgency Requirement Changes



The peak data rate requirement as the bandwidth monitored increases is shown in Figure 4.6. Compared with the typical data rates for IMINT sensors, a T/FDOA system would add a small data rate burden. For forensic analysis, storage on-board the aircraft of all the emissions over the entire mission would be necessary.[26] Using a mission length of 16 hours, each additional 25kHz of bandwidth monitored increases the on-board mission storage requirement by 1.5 gigabits.

[26] This data would be transferred at the end of each mission to a more permanent storage. I expect that data would not be kept more than 30 days in the permanent storage. I do not estimate the capacity needed for more permanent storage.

3135 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 4.6
Peak Data Rate as Bandwidth Monitored Increases

Today, the United States purchases nearly all the SATCOM used for UAS from commercial sources. Since it is contracted, there is some flexibility in the availability of SATCOM. However, there would likely be some additional cost for providing the additional SATCOM for T/FDOA, even if the data rate burden is small. I did not estimate the additional cost of the SATCOM.

An analysis of the cost and SWAP implications of integrating a T/FDOA capable SIGINT system on UAS are outside the scope of this research; however, we can use the Harm Targeting System Revision 7(HTS R7) as an upper bound. The HTS R7 is a T/FDOA capable system that grew out of DARPA's AT3 program. Hosted on F-16 Block 50/52s, the HTS R7 enables these aircraft to cooperate to quickly locate and target surface-to-air missiles (SAMs). Each HTS R7 pod is approximately 1.2m long, with a diameter of 0.2m, and weighs 100lbs (ACC Public Affairs 2012). I estimate that the equipment for T/FDOA capability weighs approximately 20lbs.[27] I estimate that the power of a T/FDOA capable

[27] HTS R7 is an upgrade to the HTS R6. Primarily, the upgrade added the T/FDOA capability, including a digital receiver, GPS hardware, and Link 16 connectivity. The change in weight between HTS R7 and HTS R6

3136 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

system would range from 1 to 1.5kW.[28] The HTS R7 was procured for several years starting in 2006 at an approximate cost of $750,000 each (U.S. Air Force SAF/FM 2007).[29] The HTS R7 is much more complex and capable system than would be need to use T/FDOA geolocation on UAS. As such, I can consider it an upper bound on both the cost and SWAP implications of a T/FDOA-capable SIGINT system.

The technology for incorporating T/FDOA geolocation on UAS exists. Improvements have been made in digital receiver technology that reduce the cost and SWAP prohibitions. Many UAS are already equipped with antennas that could be used—for example, the UHF/VHF antenna on the MQ-1B. DARPA's AT3 program laid out many of the technical challenges. There are considerations for UAS that need to be explored, such as the placement of the receiver. The data rate, a limiting factor for AT3, is less of an issue for UAS because of the necessity of a large data link for transferring back other intelligence types, such as FMV. The peak data rate for T/FDOA geolocation would often be less than the data rates of typical IMINT sensors. The peak data rate could also be manipulated as shown in the analysis above to fit the mission demands.

MANPOWER FOR PED

Incorporating new sensors on UAS creates a new source of data that need to be turned into intelligence through processing, exploitation, and dissemination (PED). One of the largest drivers of manpower for UAS is PED. The Air Force's RPA Task Force estimated that for FY2011, approximately 4,750 personnel were dedicated to UAS PED alone (Menthe, Cordova et al. 2012). Each FMV CAP requires about 63 personnel for PED (Gear 2011). In this section, I estimate the manpower and cost implications of the PED for T/FDOA geolocation. I begin by outlining a potential CONOPs and organizational construct using the Air Force PED

---

was about 20lbs. Information from ACC Public Affairs (2012). Fact Sheet: High-Speed Anti-Radiation Missile Targeting System.

[28] Estimate based of ASIP-2C power requirements. For more information see Penn, B. (2008).

[29] FY 2006 funds procured 22 HTS R7 pods for $16.917 million. Additionally, an FY08 GWOT submission for $25 million was requested to procure an additional 35 HTS R7 pods. For more information see U.S. Air Force SAF/FM (2007, 2008).

3137 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

enterprise, the Distributed Common Ground System. I examine the manpower needs for two organizational constructs, one where a single operator is capable of controlling a single sensor and one where a single operator could control multiple sensors. I then estimate the cost implications of these manpower requirements.

CONOPs, Organization, and Tasks

I assume all Class IV/V UAS would be equipped for T/FDOA. Since the Air Force has majority of these assets, I use the Air Force's PED structure to investigate what the manpower requirements for T/FDOA PED might be. The Air Force operates its large UAS under the remote-split operations concept. In this concept, the aircraft are forward deployed to the operating area with a small crew. The forward crew controls the takeoff of the aircraft with a line of sight data link, then switches to a SATCOM data link and passes control to a stateside crew. The bandwidth and coverage of SATCOM also allows the PED components of the mission to remain stateside.

For the Air Force, intelligence data such as FMV collected by UAS travels through SATCOM to different PED sites in the Distributed Common Ground System (DCGS). The DCGS provides the "capability to conduct multiple, simultaneous multi-intelligence (Imagery, Signals, and Measurements and Signatures) ISR missions worldwide through distributive and collaborative operations" (AFISRAI-14-153 2009). In some cases, DCGS has the capability to control the sensors (AFISRAI-14-153 2009). I would expect that the set up for T/FDOA would be similar. The DCGS would control the SIGINT sensors for T/FDOA. All of the data gathered from these sensors would be processed within the DCGS enterprise. The geolocation from T/FDOA would be calculated at the DCGS, and the DCGS would be responsible for disseminating the intelligence. T/FDOA is a multi-platform technique. Consequently, the systems would need to be setup as "master/slaves." The operator would initiate a T/FDOA on one system, the master, and all other systems in the area would automatically tune to the frequency, the slaves.

I considered two different organizations, one where a single T/FDOA operator controls one sensor (one-to-one) and one where a single

3138 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

T/FDOA operator controls multiple sensors (one-to-many). I placed the T/FDOA PED in different settings within the DCGS. For the one-to-one construct, it makes the most sense to place T/FDOA PED with the platform PED crew. Today, the PED crew is tied to the platform it is supporting. Placing the PED for T/FDOA within the crew would keep with the focus on the crew. T/FDOA would be employed in a supporting manner to other intelligence types, and so having close contact with other crew members might facilitate employment. In the one-to-many construct, the T/FDOA PED would be done within the DCGS Analysis and Reporting Team (DART). The DART is a regionally focused fusion cell designed to correlate and synthesize the intelligence data collected from the platforms/sensors that the DCGS manages or exploits and fuse this data with external sources of intelligence. The multi-platform nature of T/FDOA and the multi-intelligence correlation for PED fits nicely with the mission of the DART. Placing the PED for T/FDOA within the DART would leverage the area focus of the DART.

Regardless of how many sensors the operator can control and where the operator is located, there are certain tasks that he or she would do. First, the operator would need to work with the contact from the ground forces to determine the frequencies of interest. In most missions, T/FDOA geolocation should be employed using prior information, as opposed to a means to discover new adversary frequencies. The operator would be in control of the receiver(s) and initiate the geolocations.[30] For example, if a known frequency became active, the operator might choose to create a new T/FDOA geolocation every time the frequency is active for more than 10secs. The operator would actively work to cross-cue with other intelligence types, including intelligence gathered from the same platform and intelligence gathered from nearby platforms. The operator would report the geolocation intelligence. For example, he or she might create a short document that shows the error ellipse, the frequency, and any other information known about the target. Finally, the operator would be

[30] It is likely possible to automate the initiation of geolocation; however, an operator would likely still verify the results before reporting the intelligence.

3139 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

responsible for sending the document to the supported unit and informing the DART for correlation with other area intelligence. Given these tasks, the operator would most likely be at least a SrA with an all-source (1N0XX), electronic signals exploitation (1N5XX), or cryptologic linguist (1N3XX) background.

PED Within Platform Crew

Today, a typical FMV crew for UAS is composed primarily of imagery specialists. The crew positions, specialties, and minimum ranks are shown in Table 4.3.

Table 4.3
UAS FMV Mission Crew Positions

Crew Position	AFSC	Rank	Previous Qualification
Mission Operations Commander (MOC)	14N	2Lt	
Imagery Mission Supervisor (IMS)	1N1 (imagery)	SSgt	IRE
Mission Planner (MP)	1N1 (imagery)	SrA	IA
Imagery Report Editor (IRE)	1N1 (imagery)	A1C	IA
Imagery Analyst (IA)	1N1 (imagery)	AMN	
Multi-Source Analyst (MSA)	1N0 (all-source)	A1C	
Screener	1N1 (imagery)	A1C	IA
TACOM	1N4 (networks)	AMN	

SOURCE: Adapted from AFISRAI-14-153V3 (2009).

The MOC and MSA are the only crew positions with defined multi-intelligence responsibilities.[31] The MOC is the overall supervisor, responsible for the direction of the ISR mission. As such, the MOC manages all SIGINT, IMINT, and/or MASINT collection. The MOC is also responsible for facilitating cross-cues in conjunction with the MSA.

[31] Both positions have additional responsibilities. For full description of roles and responsibilities see the Air Force Distributed Common Ground System Operations (AFISRA 14-153V3 2009) Attachment 2.

3140 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The MSA is responsible for collecting and maintaining the target research necessary to complete the IMINT, SIGNINT, and MASINT tasking. The MSA also coordinates with the MOC on cross-cues. In contrast, the PED crew positions for other assets with both SIGINT and IMINT missions include a position dedicated to correlating the various intelligence data collected by the platform, the correlation analyst (CAN), and several other positions with some multi-intelligence responsibilities in addition to a MOC and MSA.

The CAN is considered the focal point for multi-intelligence correlation. One of his or her responsibilities is to monitor all of the SIGINT, MASINT, and IMINT reporting and identify potential for cross-cueing and dynamic sensor re-taskings. The CAN is also responsible for coordinating with the different intelligence mission supervisors during cross-cue opportunities. The CAN has an all-source or networks intelligence background, is at least a SrA, and previously performed duties as the TACOM or MSA.

Given the tasks required for T/FDOA geolocation and the imagery expertise of current crew positions, a new position for T/FDOA PED would likely be needed. This position would be similar to the CAN position for the SIGINT crews. He or she would be responsible for the tasks outlined above for T/FDOA geolocation as well as the focal point for multi-intelligence synthesis for the crew.

PED Within DART

The DART is a relatively new concept created to add flexibility and responsiveness into the DCGS for the COIN/counterterrorism missions encountered in Operations Enduring Freedom and Iraqi Freedom. The DART construct includes five DARTs at each of the five core distributed ground station sites and additional specialized DARTs. The core distributed ground station cells are regionally focused, supporting specific theater(s). The DARTs are responsible for maintaining an overall picture of all DCGS platforms/sensors and a status of mission execution to enable ad-hoc taskings. The DARTs are also tasked to continuously monitor the overall adversary situational awareness picture for their specific area. Beyond providing situational

3141 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

awareness, the DARTs rapidly correlate data from the various intelligence sources and create integrated products for the supported units. As part of this analysis, the DART is expected to identify developing targets from the association of the disparate intelligence sources.

There is no specific guidance on positions within the DART. It is difficult to say whether the DART already has the expertise and available personnel to incorporate the T/FDOA PED tasks into the workload of an existing position; therefore, I will assume that a new position is necessary. This assumption will provide an upper bound for the manpower estimation. It is also difficult to say how many sensors a T/FDOA CAN could manage. I will analyze the manpower where control of 2-4 sensors is possible.

Manpower and Costs Implications for Approaches

The DCGS operates 24 hours, seven days a week to conduct PED for missions flown around the world. There are therefore limitations on the length of a crew duty period. A PED crew member may work a maximum crew duty of 12 hours. Crew duties are those that directly support the mission. For example, time spent preparing, planning, executing, and post-mission recordkeeping are all included. General military training and general squadron duties and tasks are not considered crew-related duties. For each CAP supported with T/FDOA PED embedded with the platform crew, we need five people to fill the one position.[32] The number of CAPs that we wish to support heavily influences the total minimum manpower requirement.

Table 4.4
Manpower for T/FDOA PED

	With Crew	With DART		
		2 Sensors	3 Sensors	4 Sensors
35 CAPs	157	79	53	40
50 CAPs	224	112	75	55
65 CAPs	291	146	97	73

[32] See Appendix D for the minimum manpower factor calculation.

3142 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 4.4 shows the minimum manpower requirement at several different CAP levels. These manpower requirements are relatively small when compared with the requirements for other aspects of the PED. There are significant manpower savings if an operator is capable of controlling multiple sensors.

I can estimate the cost implications for the minimum manpower requirements. I calculated the cost implications using the FY2011 Total Annual Composite Rates from the Military Annual Standard Composite Pay based on the President's Budget. The rate includes costs for basic pay, health care, retired pay, allowances and incentive pays, etc. Since I expect the operator to be at least a SrA (E-4), I averaged the rate for E-4 to E-6. The resulting rate was $76,680.

The cost implication per CAP is $383,400 annually for T/FDOA PED with the crew. Table 4.5 shows the estimated cost implications for T/FDOA PED at several different numbers of CAPs. Again, there are significant savings if an operator is capable of controlling multiple sensors. I estimate the maximum cost implication of T/FDOA PED to be $20.6 million for the Air Force annually. This cost would be for using T/FDOA on all planned Air Force UAS with T/FDOA PED done by a new position with one-to-one positions per CAP.

Table 4.5
Costs for Manpower for T/FDOA PED in $100,000

	With Crew	With DART		
		2 Sensors	3 Sensors	4 Sensors
35 CAPs	$12,038	$6,058	$4,064	$3,067
50 CAPs	$17,176	$8,588	$5,751	$4,294
65 CAPs	$20,626	$10,352	$6,901	$5,214

The manpower and cost implications for T/FDOA PED are minimal compared with the rest of the manpower dedicated for UAS PED. The minimum manpower requirements can be reduced by enabling one operator to control multiple sensors.

3143 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CONCLUSION

The analysis shows that small changes are needed for T/FDOA geolocation to be implemented on UAS. Each UAS would need to be equipped with a SIGINT system; however, the technology for T/FDOA already exists, and many of the pieces are already in place. For example, most UAS are already equipped with several different antennas that could provide frequency coverage of communication bands like UHF/VHF. AT3 broke through many of the technical barriers to T/FDOA. There will be unique design considerations for implementation on UAS, but these can be positive. For example, the data transfer issues would be easier on UAS because of the use of large data pipes for other intelligence distribution and C2. I caveat this research by acknowledging the difficulties that can be faced when integrating new technologies on aircraft.

Additional collection of intelligence data requires additional manpower to process, exploit, and disseminate that data as usable information. For the Air Force, T/FDOA PED would likely be done within the DCGS, similar to PED of other intelligence data. The CONOPs and tasks needed for T/FDOA PED influence the estimate of the manpower required. I let the number of sensors the operator can control vary and determine the minimum manpower required to sustain 24/7 operations. This manpower ranges from 40 to 291 people, depending on the number of sensors an operator can control and the number of CAPs of T/FDOA PED used. The cost implications of these manpower requirements range from $3 million to $20.6 million annually. The manpower and cost implications for T/FDOA PED are minimal compared with the rest of the manpower dedicated for UAS PED.

3144 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

5. How Can T/FDOA Be Leveraged in Multi-Intelligence Operations?

This chapter focuses on how T/FDOA can be leveraged in multi-intelligence operations. I first provide some background on why multi-intelligence operations are useful. I then present an example to show how T/FDOA geolocation can improve multi-intelligence operations. Finally, I investigate the command, control, and communication (C3) that would be needed for these complex operations to be successful.

Background for Multi-Intelligence Operations

There are tradeoffs between the intelligence type used and the information that can be provided. For example, IMINT can provide some identification and location, but not necessarily intent. FMV can provide identification, location, tracking, and intent, but has a very limited field of view. As targets improve their concealment, mobility, and dispersion it becomes more difficult to generate the intelligence necessary to prosecute the targets (Isherwood 2011). Fusing intelligence gathered from multiple sources provides a much more complete picture.

Table 5.1
Intelligence Types Provide Different Information About the Target

	Who	What	Where	When	Why	Field of View
SIGINT	Yes	Yes	Yes	Yes	Yes	Wide
GMTI	No	Yes	Yes	Yes	No	Wide
IMINT	No	Yes	Yes	Yes	No	Medium
FMV	No	Yes	Yes	Yes	No	Narrow

SOURCE: Adapted from Isherwood (2011), p. 20.

Layering ISR by positioning ISR assets over the same geographic areas at the same time is one way to generate intelligence that can be fused. Layering complementing ISR can provide more information about each target. For example, by fusing IMINT and SIGINT, we might be able to identify a decoy SAM from an actual SAM. Layering ISR can also

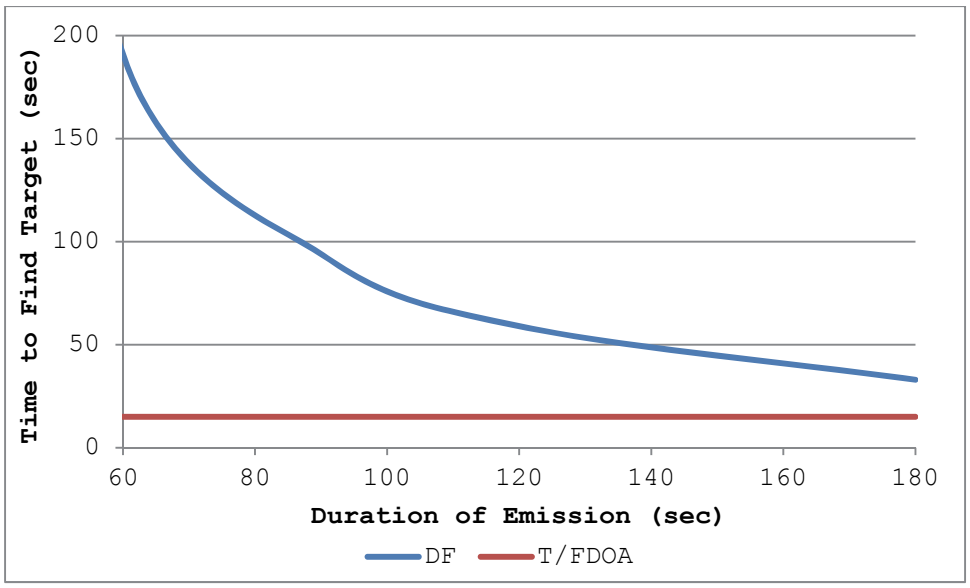
3146 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

improve the accuracy of information. For example, suspicious movement characterized by GMTI and paired with FMV could show that the movement is an illegal checkpoint set up by the enemy. These improvements in quantity and quality enhance operational decisionmaking and the ability to respond. Using SIGINT with T/FDOA geolocation on UAS would help layer at least two intelligence types for nearly every UAS mission.

Cross-cueing is defined as an exchange of intelligence data between units intended to generate additional collection on the same target/activity to create higher confidence, more accurate, or more complete reporting (480th ISR Wing 2010). It is also known as a tip-off, intended to increase situational awareness (480th ISR Wing 2010). Cross-cueing is typically thought of as cueing between the different intelligence types or assets to provide additional information. It is an important force-multiplier, allowing the complementing capabilities of each intelligence type to be focused on one target. In today's war, multiple sources of intelligence are often needed to find and locate the enemy (Isherwood 2011). One example of cross-cueing would be using the GMTI to track a target that has been geolocated from SIGINT.

Impact of T/FDOA Geolocation

Two of the advantages of T/FDOA, speed and accuracy, could significantly improve our ability to conduct multi-intelligence operations and use cross-cueing. In a cross-cue, the second intelligence type often must search a particular location to find the target of interest. For example, if trying to cue FMV from a SIGINT hit, an analyst might have to search throughout the ellipse to find the target. Therefore, the accuracy of the geolocation is a large driver of the time it can take to find the target.



Operation with Direction Finding versus T/FDOA Geolocation

I compared the time it would take to find a target using FMV if the geolocation of the SIGINT cue was accomplished using direction finding or T/FDOA. I use two UAS each equipped with FMV to search the error ellipses resulting from the geolocations. For direction finding, the length of the baseline severely impacts the accuracy of

3147 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

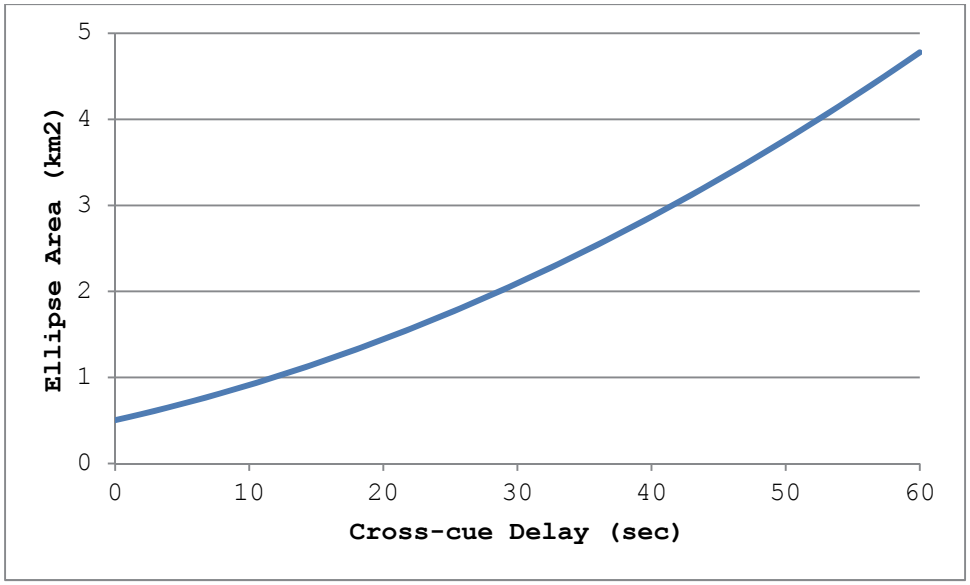
geolocation. I assume the baseline is as long as the duration of the emission. As the emission duration increases, the error ellipse shrinks, and so the time to find the target using direction finding decreases. However, as Figure 5.1 shows, using T/FDOA geolocation is better than even a baseline of more than three minutes.

Figure 5.1
Size of SIGINT Ellipse Impacts Time Needed to Find Target

NOTES: The analysis assumes a static target with the SIGINT platform in close proximity (50km) to the target. I use a report time of 10sec for the SIGINT to FMV cue. For FMV, a resolution of 0.3 meters is required. An FMV platform at 25 km range, 12.4kft altitude, equipped with a 0.16 meter diameter optic with 8 meter focal length at 0.8 micrometer (near IR) wavelength with 0.02 by 0.02 meter detector array will have a resolution of 0.3 meters (diffraction limited). The spot size would be 62.5 by 413 meters (0.02582 km2). I use a dwell time of 5sec for each FMV spot and slew time of 2sec to move the spot to a new location.

The longer FMV must search for a target, the higher the chance that the target will be lost. The accuracy of T/FDOA geolocation can greatly reduce the search time for an emitter.

In this example, the FMV platform did not need to travel a great distance to arrive at the geolocation error ellipse. Although T/FDOA geolocation can be nearly instantaneous, and therefore reduce the time to search the area, the same limitations on aircraft movement exist.



3148 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

For example, a UAS traveling at 100m/s would take over 16 minutes to travel 100km. The limitations on aircraft movement mean that the second intelligence collector must be relatively close to the target to cross-cue.

Importance of Timing

The timing of target handoffs is crucial to the success of cross-cueing. The passing of the target from one sensor/platform to another must happen very quickly, or the area that needs to be searched can grow very large. In some cases, the area grows so much that the target will be lost. Figure 5.2 shows an example of how the cross-cue delay impacts the error ellipse for SIGINT to FMV cross-cue with a moving target.

Figure 5.2
Delay in Cross-cue Increases the Area Needed to Search

NOTES: Analysis uses an initial ellipse of .50km2. Target is travelling 50 km/hr in an open area unconstrained by travelling on roads or terrain limitations.

The cross-cue delay can cause a medium accuracy error ellipse to become unusable. Cross-cueing of a challenging target, like a moving target, must happen within a minute for the cross-cue to be successful. T/FDOA geolocation meets this quickness standard. The speed of T/FDOA

3149 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

reduces the time from initial SIGINT hit to geolocation ellipse without degrading the accuracy. The near-real-time geolocation from T/FDOA can reduce the cross-cue delay in a multi-intelligence operation.

COMMAND, CONTROL, AND COMMUNICATION

Cross-cueing between intelligence types becomes more difficult and less fruitful the longer the delay between target handoff. This section examines what C3 would be required for successful multi-intelligence operations with T/FDOA and how that C3 can be provided using the emerging ISR Mission Type Orders (MTOs) concept.

What C3 Is Needed for Multi-Intelligence Operations with T/FDOA?

Cross-cueing can be very complicated. Someone needs access to the multiple streams of intelligence (HUMINT, SIGINT, IMINT, etc.) in order to determine the potential for a cross-cue. If SIGINT geolocated a target signal, but was unaware of the presence of the FMV, the cross-cue will not happen. To effectively cross-cue, the supporting unit, for example the UAS and relevant PED, should have an understanding of the situation on the ground. Knowing the commander's intent, the purpose of the operation, and other pertinent background information allows the UAS operators and PED analysts to leverage their expertise.

When responsibility is passed, the units try to avoid a "blink" where the target is lost. Latency and incompatible or incomplete data can cause a cross-cue to fail. As discussed above, the timing of target handoffs is crucial to the success of cross-cueing. The passing of the target from one sensor/platform to another must happen very quickly, or the target is easily lost.

The dynamic tasking and targeting needs to be flexible in order to deviate from the planned collection and enable collection on a cross-cue. The receiving sensor (the second or third, etc., participating in the cue) likely has some intelligence request that it is currently fulfilling. Once there is potential for a cross-cue, the authority to change the tasking for the receiving sensor needs to be immediate. This authorization needs to have prioritized the time sensitivity of this cross-cue with other requests, decided which other requests can be

3150 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

delayed or dropped, and done this within seconds. For a multi-intelligence equipped asset cueing to a second sensor on the same asset, this authorization process would likely be simpler, since they still continue supporting their primary task.[33]

Quick and clear coordination with other assets is essential to cross-cueing. Often, these assets are owned by different components and supporting different units. For these multi-intelligence operations, those involved must communicate closely with ground forces and other supporting assets. Cross-cues depend on quickly and accurately conveying information. Standardized communication practices, similar to a 9-line, would enable clear communication.

Using ISR MTOs

ISR MTOs grew out of a desire to deviate from the preplanned, rigid taskings and target decks. Joint Publication 3-50 defines MTOs as "an order to a unit to perform a mission without specifying how it is to be accomplished." An ISR MTO is typically a more narrative tasking that provides background information on the supported unit's commander's intent (Green 2011). ISR MTOs can also introduce more flexibility in the planning and integration process (Green 2011). A major difference between ISR MTOs and the traditional tasking is the establishment of direct liaison authority (DIRLAUTH), which allows the collectors and the units they are supporting to communicate and work together directly to accomplish the mission (Green 2011). DIRLAUTH encourages the collectors, the supporting unit, and the PED unit to coordinate in initial planning and C2 methods (Green 2011). Through this pre-coordination, the DIRLAUTH established by ISR MTOs fosters dynamic changes within a complex operational environment.

Using ISR MTOs meets most of the C3 demands for leveraging T/FDOA geolocation through cross-cueing. Establishing DIRLAUTH promotes pre-coordination with the ground unit, enabling communication and understanding during the mission. MTOs can also be written so that

[33] Today though, these assets are tasked with only one of their sensors as prime. Oftentimes, the other sensors are unsupported and so not available (Green 2011).

3151 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

there is flexibility with the target deck. In an MTO, the authorization to cue would be from the ground unit. Since constant communication is established, that authorization would likely be very quick.

CONCLUSION

The analysis shows that using T/FDOA on UAS would strengthen our multi-intelligence capabilities. Adding SIGINT with T/FDOA geolocation on UAS immediately creates the potential to layer complementing sensors. Since these sensors provide different information, fusing the data from layer sensors offers much more intelligence on the target. T/FDOA would improve our abilities to cross-cue. The accuracy advantages of T/FDOA with short duration emissions reduce the time needed to search for a target with a SIGINT to FMV cross-cue. Time is extremely important for a cross-cue. A cross-cue delay of more than seconds can cause the cross-cue to fail, especially with a moving target.

Multi-intelligence operations are complex and place unique demands on the command, control, and communication of airborne ISR. The new ISR MTO construct provides a unique way to support cross-cueing with T/FDOA geolocation. The establishment of DIRLAUTH enables quick communication between all the units in the operation, which is key to these operations.

3152 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

6. Conclusions and Recommendations

This research shows that DoD can better leverage UAS and improve multi-intelligence capabilities by expanding its geolocation capacity through the use of T/FDOA geolocation on UAS. I demonstrated that a T/FDOA geolocation would be useful in the context of today's operations. I outlined some requirements needed to implement T/FDOA geolocation, both on the platform and for the PED. Finally, I showed how the speed and accuracy of T/FDOA could improve multi-intelligence collection.

T/FDOA geolocation is useful against many targets, particularly those in an IW/COIN environment that are difficult to geolocate using direction finding. These difficult targets include those in lower frequencies (HF/VHF), those that limit the emission duration, and those that are farther from the receiver aircraft. Two of the major drawbacks to T/FDOA are the need for multiple platforms and the sensitivity to geometry. The drawbacks do not hinder employment of T/FDOA as a secondary capability on UAS. The orbits demanded by the primary intelligence collection do not negatively impact the accuracy of geolocation using T/FDOA. Without impacting the primary mission, UAS with T/FDOA capability would likely be within line of sight of the same targets.

Small changes are necessary to implement T/FDOA on UAS. The technology for T/FDOA capable sensors already exists. Many UAS are nearly equipped to be capable. Each UAS would need a SIGINT sensor with certain characteristics. The receiver(s) likely needs to be a digital receiver to meet the demands for precision and sensitivity. The system needs to be integrated with the GPS/INS systems of the UAS to provide the aircraft state vector with high enough precision. The new sensor would need to be integrated on the UAS. Integration issues are beyond the scope of this research. Today, one of the largest drivers of manpower for UAS is the PED needed to turn the data collected into actionable intelligence. The PED for T/FDOA would likely mirror PED for the other intelligence types. Focusing on the Air Force, this means

3154 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

that PED would be conducted within the DCGS. I present two options for organizing the PED based on how many sensors a single operator is capable of controlling. The manpower and cost implications appear to be small compared with the requirements to PED other sensors.

T/FDOA can be leveraged to improve multi-intelligence operations. Adding a SIGINT with T/FDOA capability to UAS instantly increases our ability to provide more information about targets by layering complementing ISR sensors. The accuracy and speed of T/FDOA geolocation can make a large impact in our ability to cross-cue. Cross-cueing must happen within seconds to be successful. T/FDOA geolocation provides high-accuracy geolocation very quickly, reducing the time delay between intelligence types and the area that a second intelligence, such as FMV, would need to search. For C3, the emerging ISR MTO concept meets the C3 needs for T/FDOA geolocation in complex operating environments.

This research was intended as a theoretical "proof of concept" for the use of T/FDOA geolocation on UAS. It shows what we would gain from using T/FDOA geolocation in an opportunistic fashion and as a secondary mission on UAS. There are many questions and analysis beyond the scope of this research that would need to be investigated before realizing a T/FDOA geolocation capability on UAS. This work outlined what would be necessary for a SIGINT system capable of T/FDOA geolocation. There is much more work that would need to be accomplished to create this SIGINT system. Additional sensors on a platform can cause issues with the current sensors, including SWAP trade-offs and issues from emissions on overlapping frequencies. For each platform that would host T/FDOA, the compatibility of a T/FDOA sensor with the other sensors would need to be investigated. In this work, only the cost implications of the manpower for PED were examined. The complete costs of implementation are much broader and range from costs associated with maintenance in the field to potential costs of additional bandwidth. These costs would need to be thoroughly researched. This research points out the importance of quickly transitioning between intelligence types, but does not delve into the tasking and re-tasking of sensors. The best method of tasking of multi-intelligence capable assets to leverage

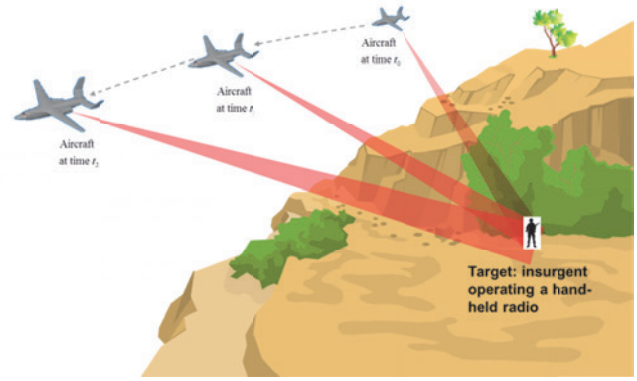
3155 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

sensors for primary and secondary missions would need to be further investigated.

There are many potential stakeholders for T/FDOA geolocation. At the DoD level, the major stakeholder is the Under Secretary of Defense for Acquisition, Technology, and Logistics (USD AT&L). Within USD AT&L, Unmanned Warfare (UW) is the lead for providing oversight of UAS acquisitions, including all subsystems such as sensors. For each individual service, stakeholders fall into similar groups. There are those that operate the UAS, those that conduct the PED for the intelligence data collected by the UAS, those that use the intelligence, and those that purchase the sensors. Each of these stakeholders will need to work together to create the most useful T/FDOA-capable sensor. Cooperation across services and organizations is important to create the most capable sensor. The accuracy of T/FDOA can be improved by increasing the number of sensors participating in the geolocation. Sensors that are interoperable are essential for T/FDOA geolocation to be the most useful.

There are several next steps that DoD should take to continue pursuing T/FDOA geolocation on UAS. This research shows how T/FDOA geolocation on UAS would complement direction finding and provide an ability to go after difficult targets in a COIN/IW environment. A full gap analysis should be done to illustrate how T/FDOA would fit in DoD's geolocation portfolio. As stated above, this research touches only on one cost implication for T/FDOA. A complete cost-benefit analysis would be needed to justify the capability. Finally, a technology demonstration would be needed before moving forward.

3156 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



APPENDIX

A. DIRECTION FINDING MODEL

DIRECTION FINDING

The military commonly uses direction finding, also known as triangulation, to fix the position of an emitter. For example, in direction finding, an aircraft would measure the angle of arrival (AOA) at multiple locations along a baseline to create lines of bearing (LOBs) between the receiver and the emitter. Two or more LOBs enable the emitter to be fixed at the intersection of these different LOBs. An example of direction finding is depicted in Figure A.1. Direction finding requires one receiver to measure the signal at one position and then move and re-measure the same signal. There are many algorithms available to calculate the emitter location. These range from plotting lines of bearing on a common map to calculations based on the various statistical techniques such as least-squares error estimation and the discrete probability density method. One of the first and classical techniques is a variant of maximum-likelihood estimation advanced by Stansfield in his "Statistical Theory of D.F. Fixing."

Figure A.1
Aircraft Calculates LOBs Along a Baseline

THEORETICAL BASIS, THE STANSFIELD ESTIMATOR

The Stansfield Estimator assumes lines of bearings are measured from multiple locations. In practice, measured bearings include both

3158 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

systematic error and random error. Typically, systematic errors are known and therefore can be accounted for in the implementation. As with successor models, Stansfield assumes that bearings are corrupted only by random errors, which are assumed to be from a Gaussian distribution with a mean of zero.[34] Stansfield uses the following geometry:

$J, K, L, M, N =$ positions of d. f. stations

$n =$ number of d. f. stations

$d =$ semi $-$ distance between two d. f. stations

$D =$ distance of point to be located from d. f. station

$D_j =$ distance from station J, etc.

$\theta =$ station bearing

$\theta_J =$ bearing from station J, etc.

$\psi =$ error in bearing

$\psi_J =$ error in bearing from station J, etc.

$p_J =$ distance from point to be located to line of bearing from station J, etc.

$q_J =$ distance from an arbitrary point to line of bearing from station J, etc.

If the true position of the emitter is unknown, but guessed to be at point S, with coordinates x,y and perpendicular distance q_J from the line of bearing of station J, then:

$$q_J = p_J + x\sin(\theta_J) - y\cos(\theta_J)$$

The equation for the likelihood of the set of position lines is then:

$$P(q_1 \dots q_n)dq_1 \dots dq_n = \frac{1}{(2\pi)^{\frac{n}{2}}\sigma_{p1} \dots \sigma_{p1}} \exp\left[-\frac{1}{2}\sum \frac{\left(p_J + x\sin(\theta_J) - y\cos(\theta_J)\right)^2}{\sigma_{pJ}^2}\right] dp_1 \dots dp_n$$

Using the following substitutions to make the equations easier to write:

[34] Stansfield validated the assumption of Gaussian with mean of zero using actual data gathered during World War 2. He removed approximately 1 percent of the bearings that were determined to have egregious errors.

3159 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

$$\lambda = \sum \left(\frac{\sin \theta_J}{\sigma_{pJ}} \right)^2 = \sum \left(\frac{\sin \theta_J}{\sigma_{\psi J} D_J} \right)^2$$

$$\mu = \sum \left(\frac{\cos \theta_J}{\sigma_{pJ}} \right)^2 = \sum \left(\frac{\cos \theta_J}{\sigma_{\psi J} D_J} \right)^2$$

$$\nu = \sum \left(\frac{\sin \theta_J \cos \theta_J}{\sigma_{pJ}^2} \right) = \sum \left(\frac{\sin \theta_J \cos \theta_J}{\sigma_{\psi J}^2 D_J^2} \right)$$

The $(\hat{x}, \hat{y})$, which maximizes the expression in the exponent above, is the best guess for the fix:

$$\hat{x} = \frac{1}{(\lambda\mu - \nu^2)} \left[\sum p_J \frac{(\nu \cos(\theta_J) - \mu \sin(\theta_J))}{\sigma_{pJ}^2} \right]$$

$$\hat{y} = \frac{1}{(\lambda\mu - \nu^2)} \left[\sum p_J \frac{(\lambda \cos(\theta_J) - \nu \sin(\theta_J))}{\sigma_{pJ}^2} \right]$$

If this is repeated, the distribution of the "optimal fixes" is:

$$P(x,y)dxdy = \frac{\sqrt{(\lambda\mu - \nu^2)}}{2\pi} \exp\left[-\frac{1}{2}(\lambda x^2 - 2\nu xy + \mu y^2) \right] dxdy$$

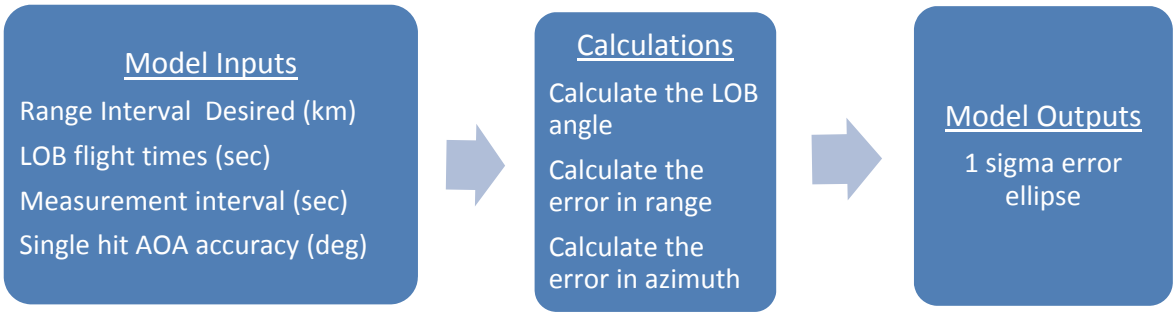
This can be transformed into

$$P(X,Y)dXdY = \frac{1}{2\pi ab} \exp\left[-\frac{1}{2}\left(\frac{X^2}{a^2} + \frac{Y^2}{b^2} \right) \right] dXdY$$

where,

$$\frac{2}{a^2}, \frac{2}{b^2} = \lambda + \mu \pm \sqrt{(\lambda - \mu)^2 + 4\nu^2}\,.$$

ERRORS



The errors that impact direction finding include measurement errors, position errors, and random errors. This model focuses on measurement error, particularly the measurement of the angle of arrival. For simplicity, the errors for AOA measurement are determined using a constant LOB angular error. This could be changed to a random draw from a normal distribution, with mean of zero and standard deviation defined by the parameter sigma.

3160 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Model Implementation

I adapted a model that had been previously used in work done for RAND's Project AIR FORCE. This model is based on the Stansfield approach described above. A graphical depiction of the model is shown in Figure A.2. The inputs are the range interval between the target and receiver (ex. 50km – 400km), the flight times of the LOBs (ex. 60sec, 120sec, 180sec), the measurement interval for each AOA (ex. 3 sec), and the single-hit AOA accuracy (ex. 0.07 deg). Using those inputs, the true LOB angle is calculated. The error in range and azimuth are then determined for each point along the range interval. These estimates are then used to create a 1-sigma error ellipse for each range increment.

Figure A.2
Graphical Depiction of Direction Finding Model

Stansfield's method is a simple method that will provide a good first cut of the accuracy. There are other, more complex and more accurate methods to estimate the error of direction finding. For the comparisons in this dissertation, Stansfield's method is a good approximation.

B. ORBIT GEOMETRY RESULTS

SCENARIO 1: TWO CIRCULAR FMV ORBITS

In this scenario, there are two UAS each flying circular FMV orbits. The orbit parameters for each case are listed in Table B.1.

Table B.1
Orbit Parameters for Scenario 1

	Aircraft 1: Circular FMV Orbit				Aircraft 2: Circular FMV Orbit			
	X Offset	Y Offset	Altitude	Radius	X Offset	Y Offset	Altitude	Radius
Case 1	150km	150km	20kft	20km	150km	150km	20kft	20km

C. CAP ALLOCATION MODEL

I used the Model Builder within ArcGIS to create the CAP model. The layout of the model is shown in Figure C.1. The model inputs are the altitude of the platforms, the number of CAPs to be modeled, and the line of sight distance to be used.

Figure C.1
CAP Model

1. Model CAP Locations

Create Random Points: Using the input for number of CAPS, random points are created within the boundaries of Afghanistan to represent the locations of the CAPs.

Add XY Coordinates: The latitude and longitude of each of these points is added to the attribute table and the point shapefile is saved.

2. Model Line of Sight Overlap

Buffer: Using the point shapefile, a ring is created around each point at the inputted line of sight distance.

Intersect: These rings are intersected with each other to determine sections that can be seen by multiple CAPs. Each intersection is a separate polygon within a polygon shapefile.

Clip: The intersected rings are cut to fit within the boundaries of Afghanistan.

Dissolve: The intersected rings are dissolved and a count field is added to keep track of the number of CAPs that have line of sight to each resulting intersection.

3. Add Areas

Project: The analysis until now has been performed using a Geographic Coordinate System. To enable ArcGIS to calculate the areas of each intersection in meters squared, the polygon shapefile needs to be projected into a Project Coordinate System. The standard WGS 84 to Plate Carree transformation is used.

Dissolve (2): The intersected polygons are dissolved based on the number of CAPs that have line of sight to each area. The result is a polygon shapefile with a polygon for example the areas that can be seen by 2 CAPs, and a separate polygon for the areas that can be seen by 3 CAPS, etc.

Add Field/Calculate Field: A field for the percentage area is added and calculated. A polygon shapefile with the polygons and areas by the number of CAPS is saved.

This is repeated with a third dissolve to determine the area that can be seen by at least 2 CAPs. A polygon shapefile with the polygon and area for what can be seen by at least 2 CAPs is saved.

3174 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

D. MANPOWER CALCULATIONS

I used Air Force Manual 38-208 Volume 2 to calculate the Minimum Manpower Factor (MMF) as follows:

$$MMF\ per\ CAP = \frac{(Days/Wk)(Hrs/Day)(4.348\ Wks/Mo)(DRF)(Crew\ Size)}{Manhour\ Available\ Factor\ \times Overload\ Factor}$$

I used the man-hour available factor and overload factor for a military work force on a 40-hour workweek.

$$MMF\ per\ CAP = \frac{(7)(24)(4.348\ Wks/Mo)(1)(1)}{151.5\ \times 1.077}$$

$$MMF\ per\ CAP = 4.476$$

The total MMF depends on the number of CAPs used for T/FDOA geolocation.

$$Total\ MMF\ = MMF\ per\ CAP\ \times Number\ of\ CAPs$$

DEPARTMENT OF THE ARMY
DEPUTY CHIEF OF STAFF, G-8
700 ARMY PENTAGON
WASHINGTON, DC 20310-0700

MAY 16 2012

Today we are faced with uncertain strategic and operational environments coupled with fiscally constrained resources. The Army's equipment modernization strategy reflects the need to support the current fight, respond to uncertainties and implement the Army strategy for the force in 2020 all nested with DOD's strategic guidance. This strategy is focused on equipment needed to deter and defeat hybrid threats. We will network the force; replace, improve or transform our combat platforms; and empower, protect, and unburden our Soldiers.

The Army Equipment Modernization Plan 2013 describes the Research, Development and Acquisition (RDA) portion of our Fiscal Year 2013 President's Budget request which reflects the Army's priority materiel programs and identifies the critical capabilities to succeed in the full range of missions while maintaining a decisive advantage over any adversary.

The Army must continue to develop and field a versatile and affordable mix of equipment. The balanced approach to achieving this goal contains three main principles: integrated capability portfolios that align our equipment modernization communities to identify capability gaps and eliminate unnecessary redundancies, incremental modernization to deliver new and improved capabilities, and Army force generation processes to ensure unit equipment readiness.

Although we are a force in transition, we must continue to provide the Nation with the best equipped, most modernized, and highly capable Army to prevail in any operational environment. We will do this with affordability as our watchword and remain committed stewards of our Nation's resources. With a balanced equipment modernization strategy, the Army will remain on track to equip the Army of 2020.

DONALD C. TISON
Acting Deputy Chief of Staff, G-8
